Abstract

Different from classical semiconductor photovoltaic devices, for ferroelectric photovoltaic devices, the open-circuit voltage (V_{oc}) can be four and even more orders of magnitude larger than the band gap of the ferroelectric, and the built-in electric field arising from the remnant polarization of the ferroelectric is throughout the bulk region, which is good for obtaining giant power conversion efficiency. Among ferroelectric materials, BiFeO_3 with remnant polarization of as high as $-100 \mu\text{C}/\text{cm}^2$ has the narrowest direct band gap (-2.7 eV). These indicate that high power conversion efficiency may be obtained in BiFeO_3 -based photovoltaic devices. Also, some significant research results about photovoltaic effects of BiFeO_3 materials have been recently acquired. In order to better promote the development of BiFeO_3 -based photovoltaic devices, in this paper, we present a comprehensive review on the latest research progress in photovoltaic effects of BiFeO_3 materials with different kinds of topography, including bulk, thin film, and nanomaterials.

Built-in electric field
Ferroelectric photovoltaic effect

1. Introduction

With the increasing global energy crisis and environmental issues, the development of clean and sustainable energy has become a major issue that governments need to address urgently in the worldwide. Solar energy is one of the most important sources of renewable energy due to its clean, pollution free and wide distribution area [1,2].

In the current solar cell market, the commercialized crystalline silicon solar panels have high and stable conversion efficiency ($> 26\%$) and thus occupy most of the market share, while, their manufacturing and installation costs are high [1,3,4]. In order to reduce the cost, the second and third generation semiconductor solar cells, such as thin film, amorphous silicon solar cells, dye-sensitized solar cells, quantum dot solar cells, organic solar, and organic-inorganic hybrid perovskite solar cells have been recently given much attention [5–9]. Generally, the photovoltaic effect includes two basic processes: (1) generation of electron-hole (e–h) pairs by photons absorption, and (2) separation of photo-generated electrons and holes to form net electric current flow [10]. In conventional p–n junction semiconductor solar cells, photons with energy higher than the band gap value are absorbed to produce e–h pairs, and then the pairs are separated by the built-in electric field that exists only in the space-charge region inside the p–n junction [11–17]. Thus, these solar cells have the following drawbacks [18–20]: (1) the open-circuit voltage (V_{oc}) is limited by the band gap of the light-absorbing semiconductor; (2) the photo-generated electrons and holes can't be effectively separated, may resulting in small short-circuit current (J_{sc}); (3) their power conversion efficiency (PCE) is limited by the Shockley-Queisser limit, which prevents any single p–n junction solar cell from converting more than 33.7% of the incident light. However, completely different from traditional p–n junction photovoltaic effects, for ferroelectric (FE) photovoltaic effects, the

photo-generated electron-hole pairs can be separated by the built-in electric field arising from the remnant polarization of the ferroelectric, as shown in Fig. 1 and thus, the V_{oc} is not limited by the band gap of the ferroelectric material [21–26]. Besides, the remnant polarization-induced built-in electric field is throughout the bulk region in ferroelectric, which is very helpful for the separation of electron-hole pairs, thus may result in large photo-current, and the photocurrent direction can be switched by changing the spontaneous polarization direction of the ferroelectric material [26]. All these provide a great potential for developing photovoltaic devices with high power conversion efficiencies and unique characteristics. Furthermore, ferroelectric materials are inexpensive, abundant, and stable, which is very beneficial to ferroelectric photovoltaic devices for the practical application [27,28].

To date, a great deal of work on the photovoltaic effect of ferro-electric materials (such as $BaTiO_3$, $Pb(Zr,Ti)O_3$, and $Bi_4Ti_3O_{12}$) has been carried out [29–31]. However, the band gap of ferroelectric materials is usually large (> 3 eV), resulting in poor absorption for the visible light,

Fig. 1. Schematic illustration of the working principle of (a) p-n junction photovoltaic devices and (b) ferroelectric photovoltaic devices.

and thus the power conversion efficiencies of ferroelectric photovoltaic devices have been still too low for practical applications. In general, common ferroelectric oxides with ABO_3 type perovskite structure exhibit wide band gaps. This arises from the large difference in electronegativities of oxygen and the transition-metal atom at the B site [32]. At the same time, in most perovskite ferroelectric materials, the transition-metal ion at the B site also plays the crucial role of driving ferroelectricity [33]. Any attempt to reduce the band gap by substitution of the B ion leads to a deterioration of ferroelectric properties [34]. Thus, in order to achieve ferroelectric photovoltaic devices with high conversion efficiency, it is urgent to develop new ferroelectric materials with both narrow band gap and large remnant polarization.

Currently, $BiFeO_3$ (BFO) has attracted considerable interest due to its high temperature ferroelectric, and magnetic ordering and has been widely used in magneto-electric random access memory, sensor and actuator, ferroelectric tunneling junctions, non-volatile ferroelectric based random access memory, etc [35–39]. In very recent, some reports have indicated that $BiFeO_3$ materials have not only large remnant polarization ($\sim 100 \mu C/cm^2$) but also narrow band gap ($< 2.7 \text{ eV}$) [40–46]. Thus, compared with $BaTiO_3$, $Pb(Zr,Ti)O_3$, and $Bi_4Ti_3O_{12}$, etc. ferroelectrics, $BiFeO_3$ materials are more suitable for developing ferroelectric photovoltaic devices with high power conversion efficiency and much work on $BiFeO_3$ photovoltaic effects has been reported [47–51]. However, no comprehensive review on the photovoltaic effect in $BiFeO_3$ -based materials has heretofore been presented.

In view of this, in this review, we review the recent progress about the photovoltaic effect of $BiFeO_3$ -based materials, including bulk, thin films and nanomaterials, which will be very helpful for developing new ferroelectric materials with both narrow band gap and large remnant

polarization, and ferroelectric photovoltaic devices with high power conversion efficiency. In addition, we give some new strategies to optimize further BiFeO₃-based photovoltaic devices.

2. Properties of BiFeO₃ related to photovoltaic effects

2.1. Crystal structure of BiFeO₃

BiFeO₃ is known to be one of the most important material that exhibits multiferroic characteristic at room temperature. It is a rhombohedrally distorted ferroelectric perovskite ($T_c = 1103$ K) with the space group $R3c$, as shown in Fig. 2(a), and shows G-type antiferromagnetism up to 643 K [52,53]. The unit cell has a lattice parameter, a_{rh} , of 3.965 Å and a rhombohedral angle, α_{rh} , of ca. 89.3-89.48° at room temperature with ferroelectric polarization along [111] pseudocubic direction [54]. The unit cell can also be described in a hexagonal frame of reference, with the hexagonal c-axis parallel to the diagonals of the perovskite cube, i.e., [001]hexagonal//[111] pseudocubic, as presented in Fig. 2(b) [52,54]. The hexagonal lattice parameters are $a_{hex} = 5.58$ Å and $c_{hex} = 13.90$ Å [54]. However, according to the recent research, the BiFeO₃ thin films grown on various substrates show different crystal structures due to the interaction between the substrate and the film [55–58]. Since the ferroelectricity needs the off-center structural distortions in the lattice, the structural distortions in the BiFeO₃ thin films may cause enhanced remnant polarization, which has also been recently confirmed by Yun et al. They prepared tetragonal BiFeO₃ thin films with remnant polarization of ~ 100 $\mu\text{C}/\text{cm}^2$ on Pt/TiO₂/SiO₂/Si substrates by pulsed-laser deposition, which lays a good foundation for developing ferroelectric photovoltaic devices with large open-circuit voltage [40].

2.2. Optical properties of BiFeO₃

Recently, several research groups have investigated the optical band gap, photoconductivity, linear and non-linear optical properties of BiFeO₃ materials, respectively [46,59]. Their experimental results showed that BiFeO₃ is a semiconductor with a direct band gap of about 2.1–2.7 eV. Theoretically, Huang et al. investigated optical properties, including the frequency-dependent dielectric function, absorption coefficient, refractive index, extinction coefficient, and reflectivity of BiFeO₃ materials by using density functional theory within generalized gradient approximation [60]. The calculated results indicated that BiFeO₃ had an indirect (very close to direct) band gap of 1.06 eV, which was formed between the top of the O 2p valence band and the bottom of the Fe 3d conduction band. Due to the strong hybridization between Fe 3d and O 2p states, the electrical properties of BiFeO₃ were considered to be determined by both the charge-transfer transitions from the occupied O 2p to unoccupied Fe 3d states, and the d-d transition between the Fe 3d valence and conduction bands. Besides, they thought although the direct band gap was reported for BiFeO₃ in the form of bulk, film, nanowire and nanotube states, those experimental data also showed an absorption onset below the band gap energy, suggesting a weak optical transition. However, experimentally, the absorption was so weak that it could be ignored, and thus BiFeO₃ was regarded by most researchers as having a direct band gap.

3. Photovoltaic effects in BiFeO₃-based materials

Recently, the application of BiFeO₃-based materials in solar cells has attracted much attention. In this section, we will discuss in detail photovoltaic effects of BiFeO₃-based materials, including bulk, thin film, and nanomaterials.

3.1. Photovoltaic effects in BiFeO₃-based bulk materials

Hung et al. prepared BiFeO₃ ceramics by using the solid-phase-reaction method and studied photovoltaic characteristics of BiFeO₃ ceramic-based photovoltaic devices [61]. They found that the photovoltaic response of the devices made from this material depended strongly on light wavelength, light intensity, and sample thickness. The thinner sample had larger open-circuit photo-voltage and short-circuit photocurrent density, which was possibly because of fewer barriers in the conducting path. Besides, near-ultraviolet illumination at $\lambda = 373$ nm induced a much stronger photovoltaic response than that at $\lambda = 532$ nm, which indicated that the photon energy at $\lambda = 373$ nm was more efficiently absorbed. Tu et al. used different metal elements to dope the A site of BiFeO₃ and obtained better photovoltaic performance in comparison with pure BiFeO₃ ceramic [62–65]. They first used calcium for A-site doping, and prepared (Bi_{0.95}Ca_{0.05})FeO_{2.975} (BFO5C), (Bi_{0.90}Ca_{0.10})FeO_{2.95} (BFO10C), and (Bi_{0.85}Ca_{0.15})FeO_{2.925} (BFO15C) ceramics by using the solid-state-reaction method to study their photovoltaic characteristics [62]. BFO10C ceramic devices exhibited a higher PCE than BFO5C and BFO15C, and the maximum PCE in ITO/(Bi_{0.90}Ca_{0.10})FeO_{2.95}/Au device can reach 0.0072%, which was larger than the maximum efficiency of -0.002% in the ITO/BFO ceramic/Au devices [51]. The heterovalent substitution for Bi³⁺ with Ca²⁺ could lead to oxygen vacancies and an iron change of Fe³⁺→Fe⁴⁺. Oxygen vacancies and the distribution of Fe³⁺ and Fe⁴⁺ ions in ceramics could affect the transport of charge carriers. All these factors caused the improvement of the PCE. Later, they introduced Ba²⁺ into BiFeO₃ to replace Bi³⁺. The ITO/(Bi_{1-x}Ba_x)FeO_{3-δ}/Au device exhibited obvious photovoltaic effects under illumination at $\lambda = 405$ nm [63]. The maximum PCE in ITO/(Bi_{0.95}Ba_{0.5})FeO_{2.95}/Au device could reach 0.006% under illumination at

$\lambda = 405$ nm. Then, they used Sr^{2+} for A-site doping [64]. The maximal PCE of 0.004% was obtained in the ITO/ $\text{Bi}_{0.95}\text{Sr}_{0.05}\text{FeO}_{2.975}$ /Au device and the external quantum efficiency (EQE) was 0.2%. They continued to use Sm^{3+} for A-site doping to prepare $(\text{Bi}_{1-x}\text{Sm}_x)\text{FeO}_3$ ($x = 0.0, 0.05, 0.10$) ceramics ($\text{BFO}100x\text{Sm}$) based photovoltaic device and measured photovoltaic properties of the device under near-ultraviolet irradiation ($\lambda = 405$ nm) [65]. The experimental results showed that $\text{BFO}5\text{Sm}$ and $\text{BFO}10\text{Sm}$ had smaller band gaps of 2.18 and 2.15 eV than pure BFO ($E_g - 2.24$ eV). The maximum PCE and EQE reached 0.37% and 4.1% in the ITO/ $\text{BFO}5\text{Sm}$ / Au heterostructure devices, respectively. They thought the domain structures and hybridization between the O 2p and Fe 3d states play important roles for the enhanced photovoltaic response.

3.2. Photovoltaic effects in BiFeO_3 -based thin films

3.2.1. Photovoltaic effects in pure BiFeO_3 -based thin films

In BiFeO_3 thin film-based solar cells, the annealing temperature, film thickness, polarization direction, Schottky barrier, strain, etc. all have obvious impacts on the photovoltaic performance. Liu et al. prepared BiFeO_3 thin films by pulsed laser deposition at room temperature and studied the effect of the strain on the optical properties [66]. The compressively strained $\text{BiFeO}_3/\text{LaAlO}_3$ thin films had the largest band gap of about 3.12 eV, which red shifted to 2.75 eV for the tensile-strained $\text{BiFeO}_3/\text{NdScO}_3$ thin films. The reduced band gap was beneficial to the absorption of the visible light and thus improved the photovoltaic effect. This research provided a good idea for designing BiFeO_3 -based solar cells with high PCE. Later, Chang et al. studied the photovoltaic property of sputter-deposited BiFeO_3 polycrystalline films on Pt/Ti/ SiO_2 /Si(100) substrates [67]. Fig. 3 showed the average

short-circuit photocurrent density as a function of the illumination intensity. As shown in Fig. 3(a), upon increasing growth temperature (T_g) of the thin film, the short-circuit photocurrent density at a laser intensity of 220 mW/cm^2 increased from $5.1 \text{ }\mu\text{A/cm}^2$ for $T_g = 350 \text{ }^\circ\text{C}$ to $11.7 \text{ }\mu\text{A/cm}^2$ for $T_g = 450 \text{ }^\circ\text{C}$, and then drastically decreased to $1 \text{ }\mu\text{A/cm}^2$ for $T_g = 500 \text{ }^\circ\text{C}$. The sudden drop was attributed to the appearance of the secondary phase and the rougher surface. Similarly, as shown in Fig. 3(b), when the BiFeO₃ thickness increased, the short-circuit photocurrent density enhanced from $4.3 \text{ }\mu\text{A/cm}^2$ for a thickness $t = 50 \text{ nm}$ to $14.2 \text{ }\mu\text{A/cm}^2$ for $t = 300 \text{ nm}$, and then decreased to $8.2 \text{ }\mu\text{A/cm}^2$ for $t = 400 \text{ nm}$. Biswas et al. prepared polycrystalline BiFeO₃ film on Pt/Ti/SiO₂/Si substrates and measured photovoltaic properties of the Au/BiFeO₃/Pt device [68]. When illuminated, the device exhibited a switchable photovoltaic effect under poled conditions. The measured photovoltaic effect revealed an open-circuit voltage of 0.47 V and a short-circuit current of $3.82 \text{ }\mu\text{A/cm}^2$ under an illumination of 165 mW/cm^2 . The open-circuit voltage and short-circuit current both changed upon changing the polarization direction, as shown in Fig. 4. These research results indicated the dominant role of the depolarization field rather than the interface in the photovoltaic characteristics of BiFeO₃ film. Fang et al. fabricated BiFeO₃ epitaxial films on SrTiO₃ substrates with La_{0.7}Sr_{0.3}MnO₃ (LSMO) and Pt as electrodes [69]. A more superior switchable photovoltaic response was obtained in the Pt/BiFeO₃/La_{0.7}Sr_{0.3}MnO₃ device as compared with La_{0.7}Sr_{0.3}MnO₃/BiFeO₃/La_{0.7}Sr_{0.3}MnO₃ device. To better understand how the interface affects the photovoltaic response, they turned to the energy diagram across the heterostructure (see Fig. 5). This suggested that the Schottky barrier modulation by ferroelectric polarization at the Pt/BiFeO₃ interface was mainly responsible for the photovoltaic effect, with a very small contribution from the bulk depolarization field. Peng et al. also suggested that photovoltaic effects were mainly dominated by the electrode/film interface. The modified interface state induced by the high-

temperature thermal treatment was responsible for the photovoltaic effect of the investigated polycrystalline BiFeO₃ thin-film capacitors [70]. The experimental results indicated that, not only the open-circuit voltage but also the short-circuit current density of the devices (600 and 750 nm thick) decreased with increasing annealing temperature at the top Pt/ BiFeO₃ interfaces, as shown in Fig. 6. The maximum PCE at the room temperature for 600- and 750-nm-thick BiFeO₃ thin-film capacitors were $1.1 \times 10^{-2} \%$ and $2.3 \times 10^{-3} \%$, respectively. Yang et al. researched monodomain BiFeO₃ thin films with only a single ferroelectric variant to exclude the influence of the domain walls [71]. Their experimental results showed that the bulk photovoltaic effect in Pt/ BiFeO₃/Pt devices was an independent property characteristic of non-centrosymmetric structures rather than something that originates from the ferroelectric polarization. The direction of the photovoltaic current could be tuned by adjusting the incident light polarization and working temperature (see Fig. 7). Some results in the reports from Choi et al. and Kundys et al. also showed an angular dependence of the photocurrent on the light-polarization direction [46,72]. BiFeO₃ thin films with different layers were deposited on Pt/Ti/SiO₂/Si substrates via the solution-gelation method by Gao et al. to experimentally investigate how a nonuniform electric field formed by asymmetric electrodes affected the photovoltaic properties [28]. The Au/BiFeO₃/Pt heterostructures with 11 layers and asymmetric structures showed 1.3 V open-circuit voltages and -0.242% power conversion efficiency when illuminated by sunlight (AM 1.5). Their experimental results revealed the importance of photovoltaic study in ferroelectric thin films by forming nonuniform electric fields. Kooriyattil et al. reported a remarkable photovoltaic effect in pulsed laser deposited multiferroic aurivillius phase Bi₅FeTi₃O₁₅ thin films sandwiched between ZnO:Al transparent conductive oxide top electrode and SrRuO₃ bottom electrode fabricated on amorphous fused silica substrates [73]. Significant photovoltaic

effects were observed in the device with V_{oc} of -0.14 V and J_{sc} of about 10–16 $\mu\text{A}/\text{cm}^2$. Besides, the photocurrent was found to be obviously dependent upon the polarization direction of the external electric field.

3.2.2. Photovoltaic effects in doped BiFeO_3 thin films

To further improve the photovoltaic performance of BiFeO_3 -based materials, researchers prepared various doped BiFeO_3 thin film-based photovoltaic devices. The doping serves to reduce the band gap of BiFeO_3 materials and enhance the optical absorption ability. Gao et al. studied photovoltaic properties of La-substituted BiFeO_3 films [74,75]. They grew $\text{Bi}_{0.9}\text{La}_{0.1}\text{FeO}_3$ (BLFO) thin films on $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3/\text{SrTiO}_3$ substrates by using pulsed laser deposition with Ag as top electrode. The intrinsic open-circuit voltage with no illumination was as large as 5.8 V in the device. They claimed that the polarization clearly played an essential role in the photovoltaic effects and the electro-migration of defects such as oxygen vacancies must be taken into account to understand electric-field-induced switching. They further claimed that the downward self-polarization would cause the positively charged oxygen vacancies to migrate toward the top surface to compensate for the negative polarization charge, as shown in Fig. 8. Later, in-depth study of the photovoltaic performance of these devices was done by Cao et al. [76]. With upward-polarized $\text{Bi}_{0.9}\text{La}_{0.1}\text{FeO}_3$ film, the open-circuit voltage measured at zero current was -0.64 V in the dark and varies monotonically with light intensity. Upon exposure to 50 mW light, the open-circuit voltage changed to +0.31 V. Similarly, the short-circuit current measured at zero bias was + 3.1 nA without illumination but switched to -5.12 nA under 50 mW irradiation. These results clearly indicated that the switchable photovoltaic effect originated from both the ferroelectric polarization of the $\text{Bi}_{0.9}\text{La}_{0.1}\text{FeO}_3$ films, and the accumulation and distribution of

the oxygen vacancies. In addition, the photovoltaic properties of Co-doping of BiFeO₃ thin film was also researched. Multiferroic BiFe_{1-x}Co_xO₃ ($x = 0, 0.03, 0.05, 0.1$) thin films were prepared on quartz substrates by using a sol-gel technique. The optical band gap of BiFe_{1-x}Co_xO₃ films decreased from 2.66 to 2.53 eV upon increasing the Co fraction from $x = 0$ to 0.1, as seen in Fig. 9 [77]. Similar results were obtained Bi_{1-x}Eu_xFeO₃ (BEFO_x, $x = 0, 0.03, 0.05, 0.07, 0.1$) thin films grown on LaNiO₃ (LNO)/Si (100) substrates by pulsed-laser deposition, and the band gap of the thin film decreased with increasing fraction of Eu dopant, as shown in Fig. 10 [78]. K-substituted BiFeO₃ films (BKFO) were fabricated on FTO/glass substrates by using the solution-gelation method [79]. The band gaps were 2.52, 2.59, 2.64, and 2.62 eV for the Bi_{1-x}K_xFeO₃ films with $x = 0, 0.05, 0.10$, and 0.20, respectively. The Au/Bi_{0.8}K_{0.2}FeO₃/FTO device exhibited a maximum short-circuit current density of 1.32 $\mu\text{A}/\text{cm}^2$ and maximum open-circuit voltage of 0.45 V. Their work suggested that the reduction of the resistance while maintaining the ferroelectric is the key to the promotion of the photovoltaic effect. [Bi_{0.9}La_{0.1}][Fe_{0.97}Ti_{0.02}Zr_{0.01}]₂O₇ (BLFTZO) polycrystalline thin films were fabricated on Pt/TiO₂/SiO₂/Si substrates by pulsed laser deposition [80]. The V_{oc} and J_{sc} of ZnO:Al/BLFTZO/Pt heterostructures device was - 0.022 V and - 650 $\mu\text{A}/\text{cm}^2$, respectively, after positive poling, and changed significantly to V_{oc} - 0.018 V and J_{sc} - 700 $\mu\text{A}/\text{cm}^2$ after negative poling (see Fig. 11). The switchable photocurrent and photo-voltage response were attributed to the change of the polarization direction. Doubly ions substituted [Bi_{0.9}La_{0.1}][Fe_{0.97}Ta_{0.03}]₂O₇ (BLFTO) films were fabricated on Pt/TiO₂/SiO₂/Si substrates by pulsed laser deposition, and the V_{oc} and J_{sc} for the device was 0.20 V and 1.35 mA/ cm^2 , respectively (see Fig. 12) [81]. Agarwal et al. studied the switchable photovoltaic and photodiode characteristics of Pt/ (Bi_{0.9}Sm_{0.1})(Fe_{0.97}Hf_{0.03})O₃/LaNiO₃(Pt/BSFHO/LNO) heterostructures integrated on Si (100) [82]. The maximum J_{sc} and V_{oc} of the device are respectively 303 (-

206) $\mu\text{A}/\text{cm}^2$ and -0.32 (0.26) V after upward (downward) poling at ± 8 V. Gupta et al. prepared semitransparent Au/ BiFeO₃ derivative/ITO device by using chemical solution deposition technique [83]. A/B-site substitutional modification by rare earth Ce³⁺ and Mn²⁺ at respective Bi/Fe-site in host BiFeO₃ led to the blue shift in optical band gap from 2.53 to 2.81 eV due to the decrease of the lattice parameters. While, the photovoltaic properties of the device upon doping were obviously enhanced because of the great increase of the remnant polarization. The most superior photovoltaic properties with V_{oc} of - 0.25 V and J_{sc} of - 36 $\mu\text{A}/\text{cm}^2$ are obtained in the Au/ Bi_{0.88}Ce_{0.12}Fe_{0.9}Mn_{0.1}O₃ (BCFMO)/ITO photovoltaic device.

3.2.3. Photovoltaic effects in BiFeO₃-based heterojunction thin films

Nie et al. prepared BiCrO₃/BiFeO₃(BCO/BFO) bilayer composite films by using the solution-gelation technique [84]. It was shown that enhanced ferroelectric properties were observed in BiCrO₃/BiFeO₃ bi-layer composite films resulting from the coupling between BiFeO₃ and BiCrO₃ layers and the measured leakage current density in BiCrO₃/ BiFeO₃ bilayer composite films was 1.37×10^{-4} A/cm² at an applied electric field of 67.81 kV/cm, which is decreased by one to two orders of magnitude in comparison with the pure BiFeO₃ and BiCrO₃ films. The photovoltaic spectral responses of the normalized current for BiCrO₃/ BiFeO₃ bilayer composite films presented a noteworthy red-shift towards visible region compared with pure BiFeO₃ and BiCrO₃ films. The J_{sc} and V_{oc} of the BiCrO₃/BiFeO₃ bilayer composite films under white-light illumination were much higher than those of pure BiFeO₃ and BiCrO₃ films. Chakrabartty et al. studied photovoltaic properties of periodic multi-stacking of BiFeO₃/BiCrO₃ bilayers epitaxially deposited on CaRuO₃-coated LaAlO₃ substrates by pulsed laser deposition [85]. Among of all devices, 120-nm-thick BiFeO₃-BiCrO₃ multilayer-based

device exhibited highest photovoltage of 1.2 eV, and 60-nm-thick BiFeO₃-BiCrO₃ utililayer-based device had the highest short-current of -0.013 mA/cm². Gupta et al, prepared BiFeO₃/BaTiO₃/BiFeO₃/BaTiO₃ multilayered thin film on Pt/Ti/SiO₂/Si substrates by using chemical solution deposition, as seen in Fig. 13, which showed a J_{sc} value of -12.65 μ A/cm² and a V_{oc} value of -1.43 V, obviously higher than those reported by other workers for photovoltaic device with single layer of ferroelectric materials [86]. The enhanced photovoltaic response was attributed to the high internal depolarization field caused by the large remnant polarization more effectively separating photo-generated charge carriers. A new approach of utilizing BiFeO₃ as a light-absorbing sensitizer was developed to interface with charge-transporting TiO₂ nanoparticles by Wu et al, as shown in Fig. 14 [87]. This mesoporous all-oxide architecture, similar to that of dye-sensitized solar cells, could effectively facilitate the extraction of photocarriers. Under the standard AM1.5 (100 mW cm⁻²) irradiation, the optimized cell showed an V_{oc} of 0.67 V, which could be enhanced to 1.0 V by tailoring the bias history. Besides, a fill factor of 55% was also achieved, which was much higher than those reported in previous. Fan et al. studied the photovoltaic effect in a metal/semiconductor/ferroelectric/ metal hetero-structure of In₂O₃-SnO₂/ZnO/BiFeO₃/Pt(ITO/ZnO/BFO/ Pt) multilayer thin films [10]. The device with the hetero-layered structure exhibited a J_{sc} of as high as 340 μ A/cm² and an energy conversion efficiency of up to 0.33% under blue monochromatic illumination. The significant increase of the photocurrent in ITO/ZnO/BFO/ Pt devices compared with that of ITO/BFO/Pt devices was due to the abundant e-h pairs generated by ZnO. A Schottky barrier and an n⁺-n junction were formed at the BiFeO₃/Pt and ZnO/BiFeO₃ interfaces, respectively. Therefore, two built-in electric fields appear at the two interfaces and were constructively responsible for the separation and transport of photoexcited

e–h pairs. Huang et al. fabricated p–i–n heterojunction devices based on double perovskite multiferroic $\text{Bi}_2\text{FeCrO}_6$ thin films [88]. Under 1 sun illumination, the optimized p–i–n device yielded an V_{oc} of 0.53 V and a J_{sc} of 8.0 mA cm^{-2} , leading to a PCE of 2.0%. The enhancement of the photovoltaic properties was because of the function of the two depletion regions in p–i–n hetero-structures (operative at the p–i and i–n interfaces). In very recently, Nechache prepared $\text{Bi}_2\text{FeCrO}_6$ thin film achieving simultaneously a narrow band gap of 1.4 eV and large remnant polarization by tailoring the Fe/Cr cation ordering and the ordered domain size, and obtained a PCE as high as 8.1%, which was the largest value reported in ferroelectric photovoltaic devices, in a multilayer configuration (see Fig. 15) [89]. The superior photovoltaic properties are because their broad absorption peaks covering a large fraction of the solar spectrum between the visible and ultraviolet regions, leading to a much more efficient absorption of incident radiation than each individual layer and thus obviously increased J_{sc} (20.6 mA/cm^2).

3.3. Photovoltaic effects in BiFeO_3 -based nanomaterials

BiFeO_3 -based nanomaterials mainly include nanotubes, nanofibers, nanowires, and nanoparticles. The grain sizes in BiFeO_3 -based nano-materials are generally believed to be smaller than that in ceramics and films. Sudakar et al. demonstrated a tunable band gap from 2.32 eV to 2.09 eV in phase-pure BiFeO_3 nanoparticles by controlling the particle size from 65 nm to 5 nm [90]. The reduction in the band gap with decreasing particle size was attributed to the competing effects of microstrain, oxygen defects, and Coulombic interactions. Multiferroic $\text{Bi}_{1-x}\text{Eu}_x\text{Fe}_{0.975}\text{Mn}_{0.025}\text{O}_3$ ($x = 0.025, 0.05, 0.075, 0.1$; called BEFM1, BEFM2, BEFM3, and BEFM4, respectively) nanoparticles were prepared by the solution-gelation route [91]. Co-

substitution by Eu and Mn could trigger a cubic phase transformation. The particle size in the samples decreased from 200 to 500 nm to ~100 nm after doping. UV–vis absorption spectra demonstrated a gradually decrease in the direct optical band gap from 2.40 to ~1.49 eV upon doping BiFeO₃ with Eu and Mn, implying electronic transitions between O 2*p* states and Fe 3*d* states. Han et al. prepared Na and Ru co-doped BiFeO₃ nanoparticles by using a solution-gelation method and investigated their optical properties [92]. In their work, the change in Fe–O bond length and Fe–O–Fe bond angle upon Ru substitution finally led to the shrinking of the optical band gap. BiFeO₃ nanowires were directly deposited on an electrode patterned substrate by using a solution-gelation-based electrospinning technique [93]. The measured carrier lifetimes in BiFeO₃ nanowire were three orders of magnitude greater than the values reported for the BiFeO₃ bulk. Fei et al. synthesized BiFeO₃ nanofibers via a sol-gel-based electrospinning process followed by thermal treatment [94]. The BiFeO₃ nanofibers exhibited excellent ferroelectric photovoltaic properties, with a photocurrent density of 1 mA/cm², which was about 10 times larger than the literature data for BiFeO₃ thin films (see Fig. 16). The reasons for the enhanced photovoltaic properties may be related to several factors: (1) the nanofibers were free-standing, allowing the ferroelectric domains to switch more freely and efficiently; (2) the nanofibers could trap more photons due to the geometric confinement. Recently, Khan et al. have studied the photovoltaic effect of pure and Pr/Cr-doped polycrystalline BiFeO₃ nanotubes fabricated via the wet chemical template-assisted route [95]. The PCE (~0.207%) of pure BiFeO₃ nanotubes was found to be enhanced by several orders of magnitude in comparison with that reported in bulk BiFeO₃ due to the special nanoscale geometry of the nanotubes, which could induce substantially large photocurrents. Pr-doped nanotubes provide highest values of PCE (~0.5%). The change in the values of the PCE upon

metal doping can be explained based on the change in the concentration and mobility of the photogenerated non-equilibrium carriers in the nano-tubes due to the incorporation of the dopant ions.

4. Summary and prospects

[Table 1](#) summarizes the performance of various BiFeO₃ materials, including ceramics, thin films, and nanomaterials for photovoltaic devices application. As seen, in the past few years, huge progress has been achieved in BiFeO₃-based ferroelectric photovoltaic devices. For instance, a large V_{oc} of 1.43 V was obtained in the Au/BiFeO₃/BaTiO₃/Pt device and the PCE of the ITO/Bi₂FeCrO₆/Nb:SrTiO₃ multilayer devices could be as high as 8.1%, which is comparable with those of some semiconductor photovoltaic devices [3,86,89]. However, the PCE of many BiFeO₃-based ferroelectric photovoltaic devices is still too low for practical applications. This is mainly attributed to the following two reasons: (1) although the band gap of BiFeO₃ is lower than those of conventional ferroelectric materials, it still exceeds the ideal value of ~ 1.4 eV (corresponding to the highest theoretical power conversion efficiency for single-junction photovoltaic devices), resulting in an overall poor sunlight absorption capability; (2) BiFeO₃ is an insulating material with very low electrical conductivity, thus leading to a quite small output photocurrent. Based on above discussion, it is clear that in order to improve further the PCE of BiFeO₃-based ferroelectric photovoltaic devices, it is the key to increasing the J_{sc} . Thus, in the future work, we should pay more attention to the increase of the J_{sc} in BiFeO₃ devices and focus the following aspects: (1) preparing highly crystalline BiFeO₃ thin films with minimum defects to improve carrier transportation capacity; (2) adjusting preparation or doping technology to decrease the band gap of BiFeO₃-based materials and thus allowing absorption of

more light in visible and ultraviolet regions; (3) developing BiFeO₃-based ferroelectric photovoltaic devices composed of multi-layers with various band gaps so that their absorption peaks can cover a large fraction of the solar spectrum between the visible and ultraviolet regions; (4) a cascade of BiFeO₃ with other materials, such as BiVO₄, Cu₂O, ZnO, etc. to effectively separate and collect photoexcited e–h pairs. Overall, it is expected that this review will provide some guidance in the development of BiFeO₃-based ferroelectric photovoltaic devices with large open-circuit voltage, high short-circuit, superior power conversion efficiency, good stability and long cycle life.

Figure 11

Fig. 9. $(\alpha h\nu)^2$ plotted as function of photon energy for $\text{BiFe}_{1-x}\text{Co}_x\text{O}_3$ ($x = 0, 0.03, 0.05, 0.1$) thin films. The inset shows the variation of the optical band gap of $\text{BiFe}_{1-x}\text{Co}_x\text{O}_3$ films [77].

Fig. 11. Current density as a function of applied bias voltage for $\text{ZnO:Al}/[\text{Bi}_{0.9}\text{La}_{0.1}][\text{Fe}_{0.97}\text{Ti}_{0.02}\text{Zr}_{0.01}]\text{O}_3/\text{Pt}$ heterostructures under 1 kW/m^2 illumination. The inset shows the region around the origin and identifies the values for V_{oc} and J_{sc} (red is for negative poling, blue is for positive poling, black is for no poling) [80]. Copyright 2014 American Institute of Physics (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article).

Fig. 12. Current density as a function of applied bias voltage for Pt/[Bi_{0.9}La_{0.1}][Fe_{0.97}Ta_{0.03}]O₃/ZnO:Al heterostructures obtained under 100 mW/cm² illumination. The inset shows the region around the origin and identifies the values for V_{oc} and J_{sc} (red is for illumination and black is for no illumination). A schematic diagram of a Pt/[Bi_{0.9}La_{0.1}][Fe_{0.97}Ta_{0.03}]O₃/ZnO:Al device appears in the lower right [81]. Copyright 2015 American Institute of Physics (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article).

Fig. 13. Schematic diagram depicting separation of charge carriers due to ferroelectric photovoltaic effect after illuminating of BiFeO₃/BaTiO₃ multilayered photovoltaic cell [86].

Fig. 14. Schematic device architectures of the a) planar- and b) mesostructured heterojunctions. For the planar-structured heterojunction, only the photocarriers near the BiFeO₃/TiO₂ and BiFeO₃/NiO interfaces can be separated and collected by the electrodes. On the contrary, in the mesostructured heterojunctions, the electron-hole pairs generated inside the nanosized BiFeO₃ grains can be effectively separated and injected into the m-TiO₂ and NiO, and then collected by the electrodes. SEM images of the c) planar- and d) mesostructured heterojunctions [871].

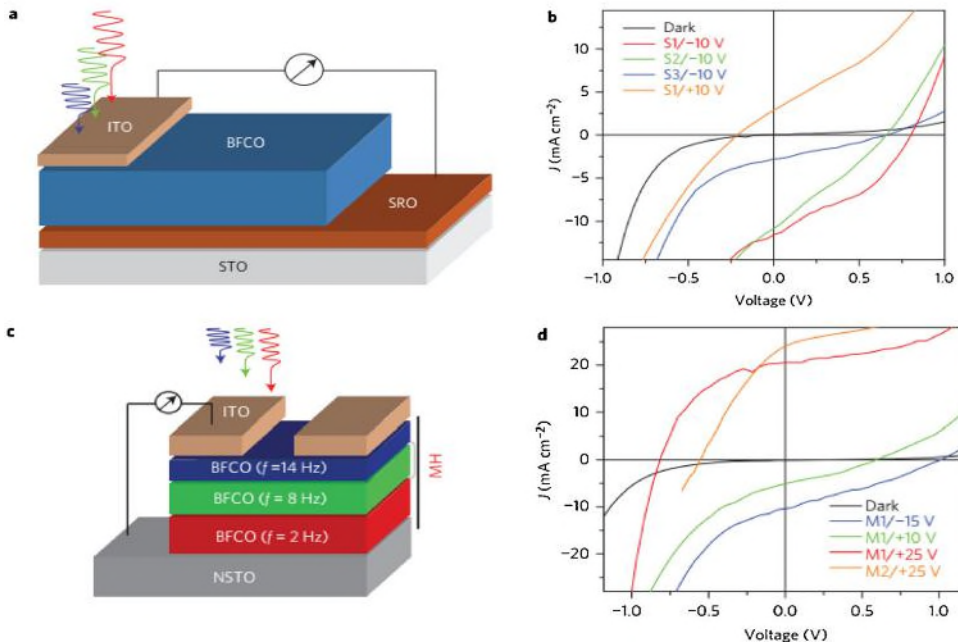

Fig. 15. (a) Layout of tested Bi₂FeCrO₆ single-layer-based structure. (b) J - V characteristics of Bi₂FeCrO₆ single-layer devices under AM 1.5 G illumination. (c) Geometry of tested Bi₂FeCrO₆ multilayer structure. (d) J - V characteristics of Bi₂FeCrO₆ multilayer devices under AM 1.5 G illumination [891].

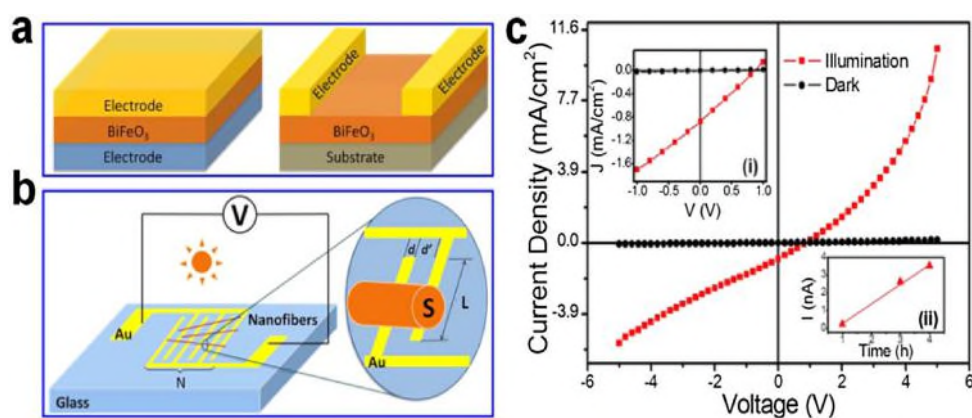

Fig. 16. (a) Schematic illustration of setup for measuring thin-film-based photovoltaic devices. The left panel shows the device in the parallel capacitor configuration. The right panel shows the device with laterally aligned interdigital electrodes. (b) Schematic setup for measuring random BiFeO₃ nanofiber-based photovoltaic devices. (c) Photoresponse profile of nanofibers. Inset (i) shows an expanded view of current density near zero bias. Inset (ii) shows the averaged photocurrent after several measurements for deposition times from 1 to 4 h [94]. Copyright 2015 American Chemical Society.

Table 1Summary of performance of reported BiFeO₃-based photovoltaic devices.

Device structure	V_{oc} (V)	I_{SC} ($\mu A/cm^2$)	Light intensity (mW/cm ²)	Light wavelength (nm)	Efficiency (%)	Ref.
ITO/BFO ceramics/Au		1.2	2	373		[61]
ITO/Ca-doped BFO	0.42	24	45.1	405	0.0072	[62]
ITO/BFO ceramics/Au			0.23	405	0.002	[51]
ITO/Ba-doped BFO	0.58	34	91	405	0.006	[63]
ITO/Sr-doped BFO ceramics/Au			125	405	0.004	[64]
ITO/Sm-doped BFO			1	405	0.37	[65]
ITO/BFO thin films/Pt		14.2	220	405		[67]
Au/BFO thin films/Pt	0.47	3.82	165			[68]
Pt/BFO thin films/Pt				404	0.011	[70]
Au/BFO thin films/Pt	1.3			sunlight	0.242	[28]
Au/BLFO thin films/LSMO	0.64			green light		[76]
Au/BKFO thin films/FTO	0.45	1.32		sunlight		[79]
ZnO:Al/BLFTZO thin films/Pt	0.022	650				[80]
Pt/BLFTO thin films/ZnO:Al	0.5	1350				[81]
Pt/BSFHO thin films/LNO	0.32	303	100	sunlight		[82]
Au/BCFMO thin films/ITO	0.25	36	160	405		[83]
Au/BFO thin films/BaTiO ₃ /Pt	1.43	12650				[86]
ZnO:Al/Bi ₅ FeTi ₃ O ₁₅ thin	0.14	16				[73]
m-TiO ₂ /BFO thin films/NiO	0.67	510	100		0.19	[87]
ITO/ZnO/BFO thin films/Pt		340			0.33	[10]
ITO/NiO/Bi ₂ FeCrO ₆ thin	0.53	8000			2	[88]
ITO/Bi ₂ FeCrO ₆ multilayer thin	0.84	20600			8.1	[89]
Ag/Pr-doped BFO NTs/Ag	0.21		10	white-light	0.5	[95]

Bismuth ferrite materials for solar cells: Current status and prospects
