Abstract: In order to research the spherical spiral groove hybrid gas bearings, the Realizable k- ϵ turbulence model of gas film was established based on FLUENT. The simulation calculation method of 6-degrees of freedom (DOF) passive grid was used, which can simulate the lubrication characteristics of the gas film transient flow field accurately. And the gas film pressure distribution and dynamic characteristic coefficients are numerically calculated. The dynamic and static pressure coupling effects of the gas flow field was analyzed and the axis motion trajectory was simulated. The effect of rotation speed, gas supply pressure and tangential angle on the dynamic characteristic coefficients during bearing operation were analyzed. And the stability of the gas bearing was studied. The conclusion from the analysis shows that different rotation speed and gas supply pressure will change the pressure distribution of the gas bearing during the operation. The dynamic characteristics of the gas film can be changed by reasonably optimizing the operation parameters, which can change the whirl characteristics of the gas film and improve the stability. Through calculation and analysis, the tangential angle is selected between 55° and 60°, both to ensure that the gas film has a high stiffness, while also can obtain the larger damping. The simulation results and the experimental results are compared and analyzed to verify the correctness and effectiveness of the simulation method. At the same time, the research of this paper provided a theoretical basis for optimizing the bearing structure and operating parameters, improving the dynamic characteristics of gas bearings and improving the operation stability.

Keywords: Spherical hybrid gas bearings; 6-degrees of freedom passive grid; Gas film pressure distribution, Dynamic and static pressure coupling effects; Dynamic characteristic coefficients; Stability

1. Introduction

Gas bearing is a new type of sliding bearing with viscous gas as the main lubricating medium, which have obvious advantages in the fields of high speed, high precision, low friction and extreme working conditions¹⁻³. The gas film with a certain bearing capacity was formed between the rotor and the stator when the bearing rotates at high speed, and the transient flow characteristics are very complex. Hybrid gas bearings has the non-linear coupling effect of static pressure and dynamic pressure. The phenomenon of whirl instability and gas film oscillation occurs at high speed, which lead to the failure of bearings and restrict the wide application of gas bearings^{4,5}. The dynamic characteristics of the gas film reflect the variation law of the gas film force when the journal deviates from the static equilibrium position and the displacement motion in the vicinity, which has very complex non-linear and stochastic characteristics. The random variation of the gas film dynamic characteristics will cause the change of the gas film motion state. It is expressed as a random change of the stability of the gas film, and directly affects the motion state of the bearing rotor⁶⁻⁸. Therefore, the calculation and analysis of dynamic characteristics of bearing gas film is the key to study the stability of gas bearing⁹.

At present most scholars have studied the stability of hybrid gas bearings basically using experimental and theoretical¹⁰⁻¹². The theoretical calculation is basically based on the Reynolds lubrication equation. The dynamic characteristic coefficients were obtained by solving simultaneously the linear equations, and the stability of the bearing was analyzed. Because the Reynolds equation can not accurately reflect the nonlinear coupling relation between the circumferential inertial effect of high speed airflow, the circumferential dynamic pressure effect of the journal and the static pressure diffusion effect, and the effect on the three-dimensional flow field characteristics. Therefore, the calculation of the stiffness and damping of the gas film deviates from the true value and the error is large. The real motion state of the bearing can not be accurately analyzed^{13,14}. However, testing the dynamic characteristic coefficients of the bearing ask for the rigorous experimental conditions. In the test process, various external factors inevitably interfere with the test, which makes the test result have certain error.

In this paper, the Realizable k- ϵ turbulence model of the spherical spiral groove hybrid gas bearings gas film was established based on FLUENT. The pressure

1 distribution on the grid point of the gas film was numerically calculated by using 6 DOF
2 passive grid. Simulating the complex gas flow in the transient flow field of the gas film.
3 The dynamic and static pressure coupling effect of the gas flow field was analyzed. The
4 dynamic trajectory of axis was simulated and the dynamic characteristic coefficients
5 were calculated. The influence law of rotation speed, gas supply pressure and tangential
6 angle on the dynamic characteristic coefficients was analyzed during bearing
7 movement. The mechanical mechanism of gas bearing stability was studied. The
8 validity and feasibility of theoretical calculation and simulation analysis were verified
9 through experimental analysis. The research provides the theoretical foundation for
10 optimizing the structure and operation parameters of hybrid gas bearings, improving
11 dynamic characteristics and improving operation stability.

24
25 This article takes the hybrid gas bearings as the research object, and the bearing consists
26 of two portions of the rotor and the stator. There is a certain number of air holes on the
27 stator, the rotor is provided with spiral grooves, the spiral groove by the groove area and
28 the platform area, as shown in figure 1. On the one hand after the introduction of
29 external high pressure gas by restrictor to bearing clearance, static gas film is formed
30 and generating in static bearing capacity. On the other hand the wedging effect between
31 rotor and stator is produced when the bearing rotates at high speed, dynamic pressure
32 gas film is formed and generating in dynamic bearing capacity. The transient flow field
33 characteristics of the gas film reflect the dynamic bearing performance and stability of
34 the bearing during the operation.

Figure 1. Spherical spiral groove hybrid gas bearings profile diagram

In Figure 1, β is the helix angle, ϕ_1 is the diameter of the bearing, ϕ_2 is the diameter of the gas supply hole, ω is the rotation speed, b_r is the table width, b_g is the groove width, h_g is the groove area clearance, h_0 is the average gas film thickness, groove depth ratio $\bar{h} = (h_0 + h_g) / h_0$, groove width ratio $\bar{b} = b_g / (b_r + b_g)$, θ for the gas supply hole angle, α_1 , α_2 , α_3 for the wrap angle, θ_1 , θ_2 is the axial supply hole angle, θ_3 is the tangential angle with reversely tangential gas supply holes.

Using the space spherical coordinate system, the model structure parameters $\beta = 70^\circ$, $R = 7.5\text{mm}$. Based on the spherical conformal space coordinate system, the spherical helix equations (1) were established in Pro / E, and the spherical helix was obtained, as shown in figure 2.

$$\begin{cases} R = 7.5 \\ \theta = \varphi \times \tan 70^\circ + 90 \\ \varphi = 360 \times t \end{cases} \quad (1)$$

Figure 2. Spherical isometric space relation diagram

The three-dimensional model of the gas film of the bearing was established by using the space spherical coordinate system, the helix and the structure parameters of the bearing. The three-dimensional gas film model of the hybrid gas bearings was established by using Pro/E. Change the default precision in Pro / E to $1\mu m$ to meet the high accuracy requirements of the model.

Model structure parameters: $\phi_1 = 15mm$, $\phi_2 = 0.2mm$, $\beta = 70^\circ$, $h_0 = 20\mu m$, $\alpha_1 = 26^\circ, \alpha_2 = 32^\circ, \alpha_3 = 85^\circ$, dimensionless eccentricity $\varepsilon = 0.3$, groove width ratio $\bar{b} = 0.4$, groove depth ratio $\bar{h} = 3.6$. The three-dimensional model of the gas film is shown in figure 3.

Figure 3. Spherical spiral groove hybrid gas bearings gas film three-dimensional model

2.2 Governing equation

In this paper, the lubrication flow field in the gas bearing can be described by the mass conservation equation and the momentum conservation equation.

(1) Mass conservation equation

$$\frac{\partial \rho}{\partial t} + \text{div}(\rho u) = 0 \quad (2)$$

Where ρ is the air density; t is the flow time; $\text{div}(\rho u)$ is the divergence of the velocity vector u .

(2) The momentum conservation equation

$$\begin{aligned}
\frac{\partial(\rho u)}{\partial t} + \text{div}(\rho u \bar{u}) &= \text{div}(\mu \text{grad} u) - \frac{\partial \rho}{\partial x} + S_u \\
\frac{\partial(\rho v)}{\partial t} + \text{div}(\rho v \bar{u}) &= \text{div}(\mu \text{grad} v) - \frac{\partial \rho}{\partial y} + S_v \\
\frac{\partial(\rho w)}{\partial t} + \text{div}(\rho w \bar{u}) &= \text{div}(\mu \text{grad} w) - \frac{\partial \rho}{\partial z} + S_w
\end{aligned} \tag{3}$$

Where μ is the dynamic viscosity; S_u , S_v , S_w is momentum conservation equation of the generalized source term; u , v , w is the velocity vector on the x , y , z direction of the velocity components.

When the transient flow field of the bearing gas film is simulated, the 6DOF solver uses the force and moments of the rotor to compute the translational and angular motion of the center of gravity of the rotor, thus obtaining the motion trajectory of the bearing rotor.

The governing equation for the translational motion of the center of gravity is solved for in the inertial coordinate system:

$$\dot{\vec{v}}_G = \frac{1}{m} \sum \vec{f}_G \tag{4}$$

Where $\dot{\vec{v}}_G$ is the translational motion of the center of gravity, m is the mass, and \vec{f}_G is the force vector due to gravity.

The angular motion of the object $\dot{\vec{\omega}}_B$ is more easily computed using body coordinates:

$$\dot{\vec{\omega}}_B = L^{-1}(\sum \vec{M}_B - \vec{\omega}_B \times L \vec{\omega}_B) \tag{5}$$

Where L is the inertia tensor, \vec{M}_B is the moment vector of the body, and $\vec{\omega}_B$ is the rigid body angular velocity vector.

After the angular and the translational accelerations are computed from Equation (4) and Equation (5), the rates are derived by numerical integration. The angular and translational velocities are used in the dynamic mesh calculations to update the rotor position.

2.3 Finite element mesh model

The gas bearing is meshed by FLUENT pretreatment software ICEM CFD. Due to the large difference in size of the hybrid gas bearings in the three directions of the space, and the gas film thickness is generally within a few tens of microns. It is more reasonable to use structured grid partition method, which can improve the precision of numerical calculation and save calculation time, and reduce the probability of the negative volume of the grid. After comparing and analyzing the calculation results of the calculation model under different grid densities. It is found that the different grid numbers in the gas supply hole and the spiral groove lead to the difference of the calculation results. The grid was properly encrypted in the position of the gas supply hole and the spiral groove, O-type grids were used in the gas supply holes. The grid of the gas film is shown in figure 4.

Figure 4. Finite element calculation model

3. Numerical calculation of flow field

3.1 FLUENT calculation model and model hypothesis

3.1.1 The flow Realizable k - ϵ model

In the dynamic calculation of the model, FLUENT mainly has active and passive grid two ways to control the model of the grid deformation. The active dynamic grid is usually used in the boundary motion law and the motion state is known. The boundary motion trajectory program is called to simulate the boundary motion, and the transient flow field characteristics of the model are calculated. The passive dynamic grid is usually used for the boundary motion and the motion state is unknown. It is often

necessary to obtain the boundary motion by calculating the force or torque on the boundary. The hybrid gas bearings motion state is unknown, it is mainly by the bearing structure parameters, rotation speed, gas supply pressure, external load and other factors. Therefore, the passive grid is more appropriate to calculate the dynamic characteristics of the bearing, and it can also simulate the motion characteristics of the bearing gas film more realistically.

The k- ϵ model of the turbulence model is a two-equation model, which contains the transport equation for the turbulent kinetic energy k and the equation for the turbulent dissipation rate ϵ . The k- ϵ model is also divided into standard k- ϵ model, RNG k- ϵ model, and Realizable k- ϵ model. The Realizable k- ϵ model is applied to the flow of higher mainstream shear rate and larger curvature. It can achieve better calculation results for the swirling flow, boundary layer flow with strong pressure gradient and complex secondary flow. Hybrid gas bearings with a smaller size, the speed can be up to tens of thousands or even hundreds of thousands during the operation. When the bearing rotates at high speed, the motion of the gas film will appear as whirl and cyclone. This model can well simulate the cyclone phenomenon at the gas supply hole. So the Realizable k- ϵ turbulence model is adopted in this paper.

3.1.2 Model hypothesis

The lubrication analysis model of the spherical helical groove hybrid gas bearings which reflects the pressure field and velocity field distribution, dynamic bearing characteristics and lubrication characteristics of the gas film in the bearing clearance. In the calculation of the fluid has the following assumptions: (1) The lubricating medium is Newton fluid, and the gas viscosity coefficient is constant; (2) There is no heat exchange between the gas and the wall, and the thermal deformation of the bearing and journal is not considered during the rotation; (3) In the direction perpendicular to the thickness of the gas film, the velocity change is neglected, that is the pressure does not change along the gas film thickness; (4) The gas does not have relative sliding on the shaft and bearing surfaces; (5) The wall is assumed to be smooth, without considering the influence of wall roughness and slip boundary.

3.1.3 Boundary conditions

The boundary conditions for flow field calculations are used for three boundary

conditions for inlet, outlet and wall. (1)The gas supply hole and large end of the gas bearing is the pressure boundary condition, the total inlet pressure is given. (2)The small end of the gas bearing is also the pressure boundary condition, and the pressure is set as ambient atmospheric pressure according to the actual situation. (3)The remaining boundary of the bearing is set as a wall surface, and there is no relative sliding between the wall surfaces. The inner wall surface of the gas film is set as a rotating rigid wall, and the outer wall surface of the gas film and the wall surface of the gas supply holes are set as fixed wall surfaces.

3.2 Steady-state solution calculation

After introducing the gas bearing grid into FLUENT, the 3D pressure base implicit solver is selected, and the boundary conditions of the flow field calculation are set up. PISO algorithm is used in the pressure and velocity coupling, and the algorithm is based on SIMPLE algorithm. The difference between the two is that after a given pressure to solve the momentum equation and the continuous equation, the PISO algorithm needs to correct the pressure and velocity equations twice, so that the pressure and velocity reach the second and third order precision of the moment. Due to the influence of the high speed rotation of the journal on the flow field, the interpolation discrete format of the pressure equation chooses PRESTO. The residual difference of all equations is less than 0.0001, and the flow rate of the inlet and outlet is monitored during the calculation. And the calculation is convergent when the numerical value is basically equal.

The steady-state calculation is based on the given structure parameters and operating parameters. It is assumed that the gas bearing can operate stably under given radial and axial eccentric conditions, and through the FLUENT simulates the flow field in the gas film thickness. The pressure field and velocity field distribution at each grid point were calculated numerically, and the steady gas film pressure distribution and the steady state bearing performance are obtained. The steady-state calculation flow chart as shown in figure 5:

Figure 5. Steady-state simulation calculation flow chart

3.3 Transient calculation

The gas bearing is based on the given structure parameters and operating parameters, and through the FLUENT simulates the flow field in the gas film thickness. The pressure distribution at each grid point of gas film are calculated numerically, and the dynamic characteristic coefficients of the bearing are obtained. The dynamic calculation flow chart as shown in Figure 6:

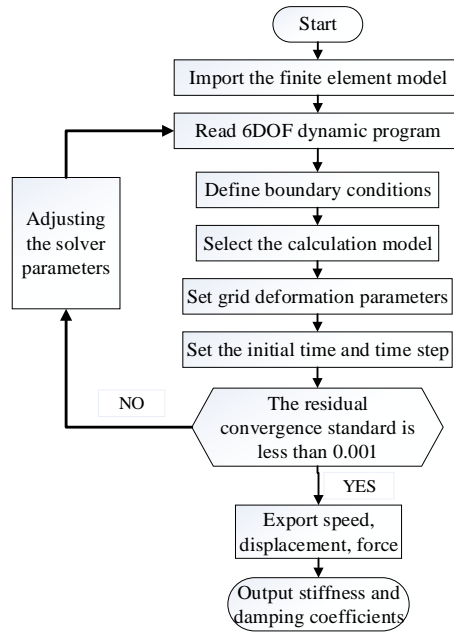

Figure 6. Dynamic simulation calculation flow chart

First, write a 6 DOF dynamic program. The meaning of 6 DOF is 6 degrees of freedom, with three translation motions and three rotational motions. The 6 DOF program can limit or release the degree of freedom required for the rotor during transient calculations. The quality and moment of inertia of the rotor can be obtained during modeling, while the 6 DOF program is programmed according to the UDF manual. Because the opposed hemispherical bearing is used in the test, the axial translation is cancelled, so the Z-direction translation freedom is limited in the simulation calculation.

In dynamic calculations, select a period of time during the simulation and output the force, velocity, and displacement of the gas film at each time step. Since the time step is very short, the rotor running state and the film force change are small in the process of output data for 5 consecutive times. So the calculation of the change of force, velocity and displacement starts from the sixth groups, and then the dynamic stiffness damping coefficient of the gas film is calculated by Equation (6). According to the above method, the Matlab program is compiled, and the rolling iteration method is used to process and calculate the data. Finally, obtain the average value to obtain the dynamic stiffness damping coefficient of the bearing.

$$\begin{cases} \Delta F_x = k_{xx} \cdot \Delta x \\ \Delta F_x = k_{xy} \cdot \Delta y \\ \Delta F_y = k_{yx} \cdot \Delta x \\ \Delta F_y = k_{yy} \cdot \Delta y \end{cases}, \begin{cases} \Delta F_x = b_{xx} \cdot \Delta v_x \\ \Delta F_x = b_{xy} \cdot \Delta v_y \\ \Delta F_y = b_{yx} \cdot \Delta v_x \\ \Delta F_y = b_{yy} \cdot \Delta v_y \end{cases} \quad (6)$$

Where ΔF_x 、 ΔF_y is the variation of bearings gas film force between at two time points, k_{xx} 、 k_{yy} is the direct stiffness coefficients, k_{xy} 、 k_{yx} is the cross stiffness coefficients, b_{xx} 、 b_{yy} is the direct damping coefficients, b_{xy} 、 b_{yx} is the cross damping coefficients, Δx 、 Δy are displacement variations of bearings in the X and Y directions respectively, Δv_x 、 Δv_y are the velocity variations of the bearing in X and Y direction respectively.

4. Pressure distribution and dynamic and static pressure coupling effects

The gas film pressure distribution of the hybrid gas bearings is mainly influenced by the operation parameters and the structure parameters of the bearings. The influence of gas supply pressure and rotation speed on the stability of bearings was studied by the pressure distribution characteristics of the bearings gas film¹⁵⁻¹⁷.

Pressure nephogram of three dimensional gas film pressure of hybrid gas bearings when gas supply pressure is 0.2MPa and rotation speed is 30000r/min.

Figure 7. Gas film pressure nephogram of bearing

As can be seen from Figure 7, due to the existence of bearing eccentricity, the gas flow has a wedging effect when the bearings is running. And the convergence region and the divergence region are formed in the gas film thickness. The gas film pressure in the convergence region is gradually increased, the gas film pressure is the

largest in the area near the smallest gas film thickness. The gas film pressure in the divergence region is decreasing rapidly. The gas film pressure is abrupt change at the junction of the groove table of the bearings spiral groove. The gas film pressure at the junction of the side of the increased sharply, the other side plummeted. The dynamic pressure effect is significantly enhanced when the bearing rotation speed is gradually increased.

Figure 8. Gas film circumferential pressure distribution

Figure 8 shows the pressure distribution of the gas film on the different circumference sections of the bearings when the rotation speed is 30000r/min; Figure 8b is the distribution of gas film pressure at different rotation speeds of the spiral groove section of the bearing when the gas supply pressure is low. It can be seen from the figure that the static pressure effect is obviously enhanced near the bearing supply holes and the dynamic pressure effect appears near the spiral groove. The pressure of gas film increases with the increase of rotation speed, and the dynamic and static pressure coupling effects was formed to bear the bearing capacity of gas film. And makes the pressure distribution in the circumferential direction more uniform, load distribution more reasonable. The dynamic pressure effect is greatly influenced by the rotation speed. The higher the speed, the greater the eccentricity, which makes the dynamic pressure effect more obvious. In order to obtain larger bearing capacity, gas bearings need to increase the spiral groove and other structures, increase eccentricity, reduce the average gas film thickness to enhance the dynamic pressure effect. However, the gas film force which leads to the gas film whirl is increased, and the typical whirl phenomenon is caused. When the whirl is larger, the amplitude increases, which is the important reason of rotor instability. Hybrid gas bearings can enhance the static pressure effect by increasing the gas supply pressure to improve the bearing performance while

maintaining reasonable dynamic pressure effect. While greatly improving the bearing capacity, it is also more conducive to better guarantee the stability under large load.

When the rotation speed is high, the bearing capacity generated by static pressure effect of bearings increases slowly with the increase of the gas supply pressure. At this time, the dynamic pressure effect increases greatly due to the high rotation speed, which makes the static pressure and dynamic pressure coupling effect bearing capacity stronger. Therefore, dynamic and static pressure coupling effects can complement each other better, which can not only enhance the bearing performance of the gas film, but also optimize the dynamic characteristics. It can effectively restrain the generation of whirl and oscillation, and improve the stability of high speed operation.

5. Axis dynamic trajectory simulation

During the operation of the hybrid gas bearings, the different axis trajectory can reflect the motion state and the fault information of the bearing. The stability of the bearing can be judged by the convergence and divergence of the bearing axis trajectory¹⁸⁻²⁰. There are many factors that affect the axial trajectory of the hybrid gas bearings, such as gas supply pressure, rotor speed, bearing structure parameters, external disturbances and so on. In this paper, the influence of rotation speed on the axial trajectory of hybrid gas bearings was studied. Through simulation of bearing axis trajectory diagram and spectrogram, the influence on gas film stability was analyzed.

Figure 9. 10000r/min axis trajectory diagram and spectrogram

Figure 10. 17500r/min axis trajectory diagram and spectrogram

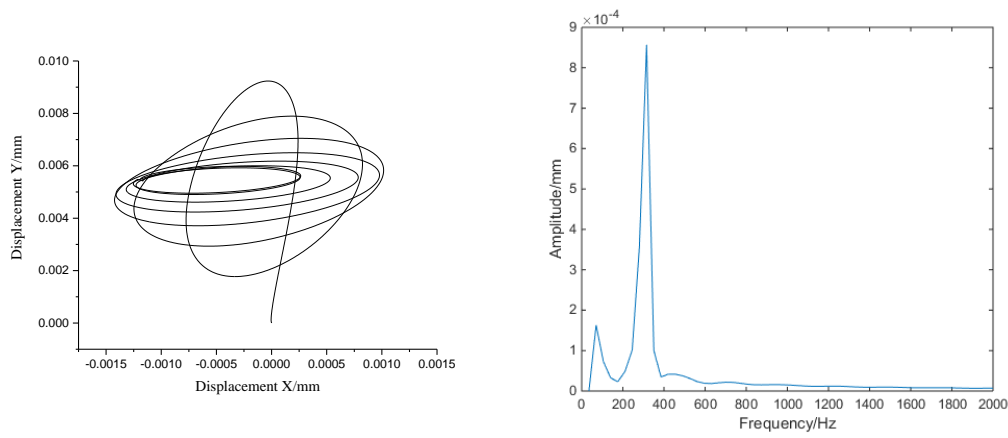

Figure 11. 20000r/min axis trajectory diagram and spectrogram

Figure 12. 30000r/min axis trajectory diagram and spectrogram

Figure 13. 40000r/min axis trajectory diagram and spectrogram

Figure 14. 50000r/min axis trajectory diagram and spectrogram

Figure 15. Variations of the amplitude in x and y direction with rotation speed

Figure 15 shows the stability characteristics of the bearing was analyzed on the variations of the amplitude at x and y direction with respect to rotational speed. From Figure 9 to 11, when the bearing rotation speed is 10000r/min, the axis trajectory is the

standard ellipse. The motion belongs to the same frequency whirl, which is still linear stability. With the rotation speed increases to 20000 r/min, the amplitude increases first and then decreases. When rotation speed in the 17500 r/min, the corresponding spectrogram shows the maximum value of the working frequency amplitude. And the first-order critical speed of the system is appeared, at this time the bearing is still stable. As can be seen from Figures 12 to 14, when the rotation speed is gradually increased from 20000 r/min to 40000 r/min. The axis trajectory diagram shows that the running state changes from quasi-periodic motion to periodic motion, and the amplitude shows an increasing trend. And the whirl energy of the bearing increases gradually, and the axis trajectory gradually diverges. When the rotation speed reaches 40000 r/min, the vibration of the bearing appears the relatively weak half-frequency and double-frequency. When the rotation speed increases to 50000 r/min, the half-frequency is obviously enhanced, and the axis trajectory also has obvious half frequency whirl.

6. Dynamic calculation and stability analysis

6.1 Variation of rotation speed on dynamic characteristic coefficients

When the dynamic pressure gas bearing is running at high speed, the change of the operation parameters (rotation speed, gas supply pressure, external load, disturbance frequency) will cause the change of the flow field inside the gas film, and the characteristics of the gas film will be reconstructed. It will cause the change of the eccentricity, the pressure distribution of the gas film, the nonlinear gas film force, the bearing performance, the dynamic characteristic and the stability²¹⁻²². Figure 16 shows the variation law of the stiffness and damping of the bearing with the rotation speed.

Figure 16. Variation of rotation speed on stiffness and damping coefficients

In the case of constant structure parameters and the bearing gas supply pressure is 0.2MPa, the rotation speed of the gas bearing increases from 10000r/min to 55000 r/min. The following conclusions can be drawn:

(1) It can be seen from the figure 16a that the direct stiffness coefficient k_{xx} 、 k_{yy} increases rapidly, and the cross stiffness coefficient k_{xy} 、 k_{yx} decreases gradually. Figure 16b shows that the direct damping coefficient increases gradually, and reaches the maximum when the rotation speed is around 20000 r/min. The cross damping coefficient b_{xy} decreases rapidly, while b_{yx} decreases slowly. In the vicinity of 20000 r/min, a system natural first-order critical speed of 17500 r/min appeared, and the corresponding spectrogram shows the maximum value of the working frequency amplitude. Below this speed, the axis trajectory diagrams shows linear stability period 1 motion.

(2) When the rotation speed is increased to 40000 r/min, the direct stiffness coefficient k_{xx} 、 k_{yy} is unchanged. But the cross stiffness coefficient k_{xy} 、 k_{yx} gradually increased and the damping coefficient trend is basically unchanged. When the rotation speed is increased to 45000 r/min, the spectrogram shows the phenomenon of half frequency whirl, and the axis trajectory diagrams shows non-linear stability period 2 motion. It shows that the increase of cross stiffness coefficient leads to the gas film whirl force is greater than the damping, and the gas film whirl occurs.

(3) When the rotation speed is between 40000 r/min and 50000 r/min, the stiffness and damping changed unregularly. The direct stiffness coefficient k_{xx} gradual from decrease to increase, k_{yy} from increase to decrease. The direct damping coefficient b_{xx} 、 b_{yy} from gradually decreased to gradually increased, and the cross damping coefficient b_{xy} decreases significantly. In this process, the period 2 motion and the chaotic trajectory appears repeatedly.

(4) When the rotation speed reaches 55000r/min, the direct stiffness coefficient k_{xx} from increase to decrease, while the k_{yy} rapidly increases. The cross stiffness coefficient k_{xy} 、 k_{yx} appear downward trend. The direct damping coefficient b_{xx} 、 b_{yy} changed from increased to rapidly decreased, and the cross damping b_{xy} 、 b_{yx} decreased to almost zero.

6.2 Variation of gas supply pressure on dynamic characteristic coefficients

Under the condition of 20000r/min rotation speed, the variation of gas supply pressure on stiffness and damping coefficients were simulated by changing the gas supply pressure.

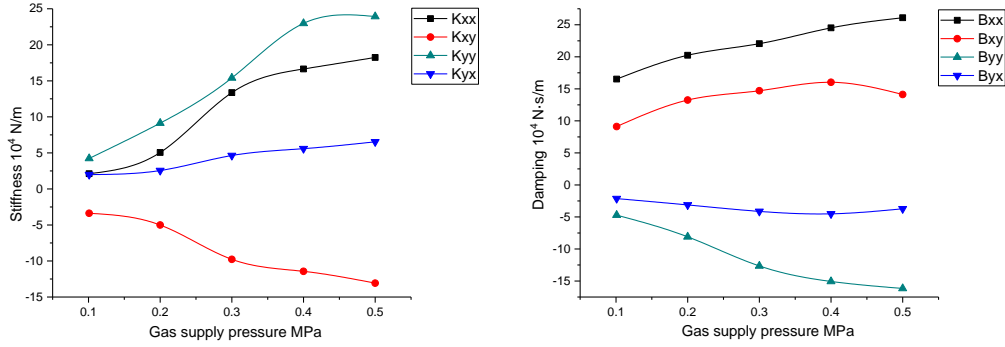

Figure 17. Variation of gas supply pressure on stiffness and damping coefficients

As shown in figure 17, with the increasing of gas supply pressure, the direct stiffness coefficients k_{xx} and k_{yy} direction are the same and the trend is increasing. At the same time, the cross stiffness coefficients k_{xy} and k_{yx} gradually increase, but the trend is slow. When the gas supply pressure exceeds 0.4MPa, the increasing trend of direct stiffness coefficients are slowed down. With the increasing of gas supply pressure, the direct damping coefficients b_{xx} and b_{yy} direction are the opposite and the trend is increasing. The cross damping coefficients b_{xy} , b_{yx} direction opposite and gradually increases, but the trend is slow. When the gas supply pressure exceeds 0.4MPa, the cross damping coefficients b_{xy} , b_{yx} gradually decrease.

When the gas supply pressure is 0.1MPa, the bearing operation is close to the pure dynamic pressure bearing. When the gas supply pressure exceeds 0.4MPa, the bearing operation is close to pure static pressure bearing. The stability of the bearing is continuously improved with the increase of gas supply pressure.

6.3 Variation of tangential angle on dynamic characteristic coefficients

The change of the structure parameters of the gas bearing directly changes the geometrical structure of the gas film, thus changing the lubrication characteristics and dynamic characteristics of the gas film during high speed operation. For hybrid gas

bearings, the main structure parameters are tangential angle, groove width ratio, groove depth ratio, helix angle and slot number. Changing the tangential angle can produce the circumfluence effect to reconstruct the dynamic characteristics of the gas film, which can change the coupling relationship between the natural frequencies of the system and the vortex frequencies of the gas film, and improve the stability of the bearing during high speed operation²³⁻²⁴.

Figure 18. Variation of tangential angle on stiffness and damping coefficients

As shown in Figure 18, with the increase of the tangential angle, the direct stiffness coefficients k_{xx} and k_{yy} of the bearings increase first and then decrease. When the tangential angle exceeds 60°, the direct stiffness coefficient k_{xx} and k_{yy} rapidly decrease. The cross stiffness coefficients k_{xy} and k_{yx} also showed a similar trend, but the trend of change was slow. The stiffness coefficient k_{yy} in the load direction is larger than the stiffness coefficient k_{xx} in the non-load direction. When the tangential angle is 55°, the stiffness of the bearing is the largest. And the damping coefficient b_{yy} in the load direction is smaller than the damping coefficient b_{xx} in the non-load direction. With the increasing of tangential angle, b_{yy} and b_{xx} showed increasing trend, which increased obviously in the 50°-60°.

As shown in figures 19, the rotation speed is the 20000r/min axis trajectory diagram, when the tangent angle is 75° and 30°.

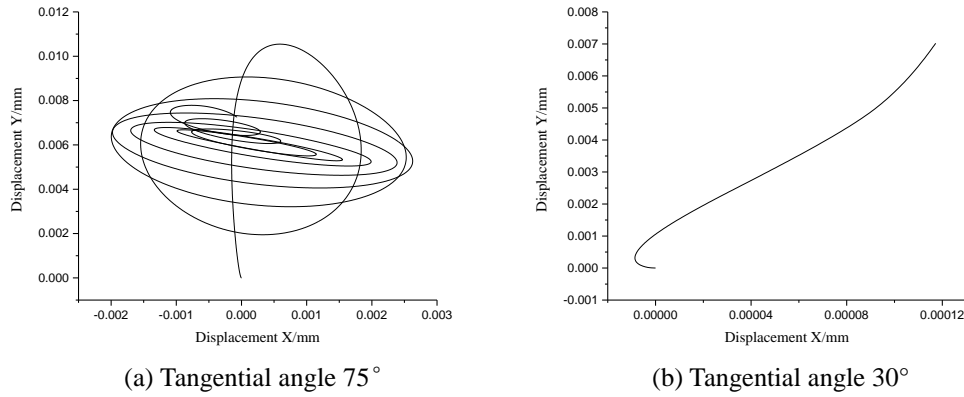

Figure 19. Axis trajectory diagram

When the tangential Angle is 75° , bearing stiffness is small, but has a larger damping. At this time, the gas film whirl force is smaller than the damping and the whirl energy is decreasing, the axis whirl trajectory is convergent. The increase of damping maintains the whirl stability. When the tangential angle is 30° , bearing stiffness is large, but the damping of the system is very small. Simulation calculations in a very short period of time will be error, resulting in the calculation can not proceed, the axis trajectory as shown in Figure 19b. At this time, the bearing gas film whirl force is greater than the damping, gas film force work to promote the whirl energy continues to increase, which leads to the axis trajectory movement divergence. Therefore, the tangential angle is selected between the 55° - 60° , which can ensure the bearing gas film has higher stiffness, but also has a larger damping coefficient, to ensure more stable and high-speed operation of the bearings.

7. Experimental verification

7.1 Test principles

This experimental test system includes high pressure gas source I, bearing test machine II, signal detection system III, data processing system IV, the overall scheme as shown in Figure 20. The equipment 1-6 connected to form a high-pressure gas source I that provides the gas supply pressure of 0.8MPa and the gas supply flow rate of 2.4 L/min. The high-pressure gas source I provides high-pressure gas to the bearing testing machine II, a part of which is used as a supporting gas to supply the gas bearing, and the other part is used as a power gas supplying turbine to drive the bearing rotor to rotation.

The signal detection system III measures the gas film force, vibration displacement, vibration speed, and rotation speed of the gas bearing in the X, Y, and Z directions. The data processing system IV processes and calculates test data to obtain the gas film stiffness and damping coefficients.

7.2 Main structure of test machine

The main structure of bearing test machine is shown in Figure 21. The gas bearing test machine is mainly composed of bearing rotor system, driving turbine, bearing seat and frame. The hemispherical diameter of the bearing testing machine is 15mm and the gas film thickness is 10 μ m. The structure parameters are shown in Table 1.

Table 1. The design parameters of hybrid gas bearings

Structure name	Parameter
Bearing diameter ϕ_1 (mm)	15
Groove depth ratio \bar{h}	3.6
Groove width ratio \bar{b}	0.4
The number of grooves N_g	6
Helix angle β ($^\circ$)	70
The average gas film thickness h_0 (μm)	20
Small hole diameter ϕ_2 (mm)	0.2
Gas supply hole row number	2
Number of gas supply holes	6

7.3 Experimental test

7.3.1 Bearing rotor critical speed experimental test

The gas supply pressure of the bearing of the gas bearing test bench was adjusted to 0.2MPa for experimental testing. The turbine gas supply system was started and the rotor rotation speed smoothly increased during the period 1 of the linear stability. In the initial stage, the rotation speed of the rotor is low, the dynamic pressure effect of the gas film and the rotation inertia of the rotor are small. The pressure fluctuation of the gas supply has a significant effect on the rotor operation, and the rotor axis trajectory is

blurred. As the rotation speed increases, the rotor vibration frequency caused by the unbalanced quantity gradually approaches the natural frequency of the test machine. Resonance occurs at the first critical speed 17650r/min and the rotor vibration amplitude reaches the maximum value. Across the first critical speed, the rotor speed continues to increase in a certain range, and the rotor vibration amplitude begins to decrease. Rotor rotation inertia and radial stability increase, and the influence of gas supply pressure fluctuation on the rotor operation is reduced. The rotor vibration frequency is strengthened and gradually dominated, and the rotor axis trajectory becomes clear and presents a single ellipse. The data processing system extracts the test data of rotor speed of 9600r/min, 17500r/min, and 20300r/min, and draws the axis trajectory and spectrogram of the rotor, as shown in Figure 23-25.

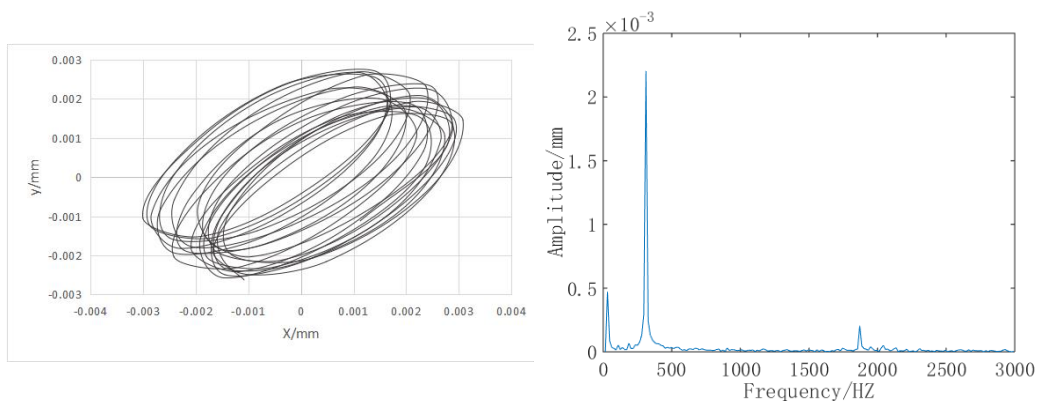

Figure 24. 17650 r/min axis trajectory diagram and spectrogram of test results

Figure 25. 20300 r/min axis trajectory diagram and spectrogram of test results

7.3.2 Stiffness and damping test

When the rotor of a gas bearing is running, the rotor deviates from the steady state of equilibrium and moves around it. The relation expression of the displacement disturbance and the velocity disturbance and the increment of the gas film force is expressed, combined with the bearing rotor the system dynamics equation calculates the stiffness and damping coefficients of the gas film.

When the bearing rotor axis moves slightly in a static equilibrium position, the linear increment of the gas film force is expressed as:

$$\begin{cases} \Delta F_x = F_x - F_{x0} = k_{xx}\Delta x + k_{xy}\Delta y + b_{xx}\Delta \dot{x} + b_{xy}\Delta \dot{y} \\ \Delta F_y = F_y - F_{y0} = k_{yx}\Delta x + k_{yy}\Delta y + b_{yx}\Delta \dot{x} + b_{yy}\Delta \dot{y} \end{cases} \quad (7)$$

When the rotor moves slightly in a static equilibrium position, the rotor center deviates from the static equilibrium position in x and y directions. The instantaneous operating parameters are $\Delta x, \Delta y, \Delta \dot{x}, \Delta \dot{y}, \ddot{x}, \ddot{y}$, and the corresponding increment of the gas film force is $\Delta F_x, \Delta F_y$. The dynamic equations of the bearing rotor system are as follows:

$$\begin{cases} m\ddot{x} + \Delta F_x = 0 \\ m\ddot{y} + \Delta F_y = 0 \end{cases} \quad (8)$$

The stiffness damping model equation of the gas film can be obtained by simultaneous equation (7) and equation (8).

$$\begin{cases} m\ddot{x} + k_{xx}\Delta x + k_{xy}\Delta y + b_{xx}\Delta\dot{x} + b_{xy}\Delta\dot{y} = 0 \\ m\ddot{y} + k_{yx}\Delta x + k_{yy}\Delta y + b_{yx}\Delta\dot{x} + b_{yy}\Delta\dot{y} = 0 \end{cases} \quad (9)$$

Solving the gas film stiffness and damping coefficient of the model equation (9), and the constant coefficients of the model equation must first be obtained. And the constant coefficients $\Delta x, \Delta y, \Delta\dot{x}, \Delta\dot{y}, \ddot{x}, \ddot{y}$ can be obtained by data pretreatment.

To solve for the gas film stiffness and damping coefficient, each equation in Equation (9) must consist of four different equations, where the determinant of the coefficient matrix is nonzero.

During the experiment, the sampling frequency of the data collection system is very high. It is considered that the rotor only undergoes minute movements during the four sampling processes, and the rotor operation state and the gas film force change are small and negligible. Therefore, the preprocessed data of the first to fourth sampling in the MYSQL database are substituted into the model matrix equation 9 for calculation, and the stiffness and damping coefficient of the gas film at the fourth sampling can be obtained. According to the above method, the Matlab program for the stiffness and damping coefficient of the gas film is compiled, and the rolling iteration method is used to process and calculate the test data, and the stiffness and damping coefficient of the gas film of the bearing rotor is obtained.

$$\begin{bmatrix} \Delta x_{n-3} & \Delta y_{n-3} & \Delta\dot{x}_{n-3} & \Delta\dot{y}_{n-3} \\ \Delta x_{n-2} & \Delta y_{n-2} & \Delta\dot{x}_{n-2} & \Delta\dot{y}_{n-2} \\ \Delta x_{n-1} & \Delta y_{n-1} & \Delta\dot{x}_{n-1} & \Delta\dot{y}_{n-1} \\ \Delta x_n & \Delta y_n & \Delta\dot{x}_n & \Delta\dot{y}_n \end{bmatrix} \times \begin{bmatrix} k_{xx_n} & k_{yx_n} \\ k_{xy_n} & k_{yy_n} \\ b_{xx_n} & b_{yx_n} \\ b_{xy_n} & b_{yy_n} \end{bmatrix} = \begin{bmatrix} m\ddot{x}_{n-3} & m\ddot{y}_{n-3} \\ m\ddot{x}_{n-2} & m\ddot{y}_{n-2} \\ m\ddot{x}_{n-1} & m\ddot{y}_{n-1} \\ m\ddot{x}_n & m\ddot{y}_n \end{bmatrix} \quad (10)$$

The bearing gas pressure of the gas bearing test bench is adjusted to 0.3Mpa for test. The data processing system extracts the test data of the gas film force, vibration displacement, vibration speed and rotation speed of the rotor of 10000r/min, 20000r/min, 30000r/min, 40000r/min, 50000r/min and 55000r/min respectively. According to equations (10), the gas film stiffness and damping Matlab program is used to process and calculate the experimental data, and the stiffness and damping coefficient of the gas film are obtained. Finally, the stiffness and damping coefficients with an eccentricity ratio of 0.3 is extracted, and the stiffness and damping coefficient of the bearing are

obtained by the average value. The relationship between the gas film stiffness damping and the rotation speed is shown in Figure 26.

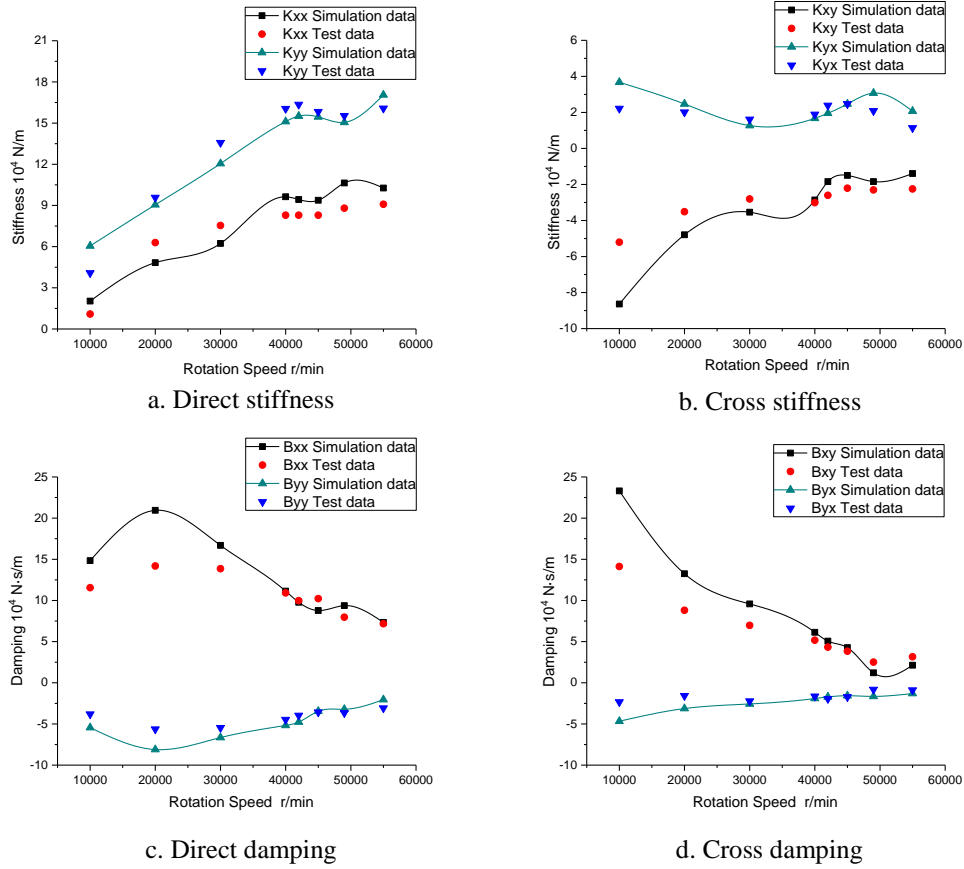

Figure 26. Comparison of simulation results and test results

The results show that the comparing the results of simulation and experimental data, the change trends of the two are consistent, and there is a certain error between the simulation results and the experimental results. The assumption of some boundary conditions is more ideal when simulating simulation calculation. And the results are related to the solver model, the grid quality, the boundary conditions and the dynamic grid model, and the parameter settings. The actual rotor mass unbalance, bearing machining error, shafting assembly error and other factors have a great influence on the test results. Therefore, there are some errors in simulation and experimental data. On the whole, the test data is consistent with the simulation results. The correctness and validity of the simulation method of 6 DOF passive grid based on FLUENT software are verified.

8. Conclusion

(1) Based on FLUENT, the pressure distribution on the gas film grid point of the hybrid gas bearings was calculated by using the 6 DOF passive grid method, which can simulate the lubrication characteristics of the gas film transient flow field accurately. Hybrid gas bearings with static pressure and dynamic pressure nonlinear coupling effect, which makes the pressure distribution in the circumferential direction more uniform and the load distribution more reasonable. Dynamic and static pressure coupling effect can not only enhance the bearing performance of the gas film, but also optimize the dynamic characteristics. It can effectively restrain the generation of whirl and oscillation, and improve the stability of high speed operation.

(2) Different rotation speed and gas supply pressure cause the change of flow field inside the gas film, which will change the pressure distribution, nonlinear gas film force, stiffness and damping coefficients during the operation of the gas film. The analysis shows that the variation of cross stiffness is the main reason of the half frequency whirl caused by the gas film whirl force greater than the gas film damping. Increasing the gas supply pressure of hybrid gas bearings will change the characteristics of the gas film flow field and improve the stiffness and damping during operation. It can effectively restrain the generation of whirl, and improve the stability.

(3) For hybrid gas bearings, changing the tangential angle can produce the circumfluence phenomenon to reconstruct the dynamic characteristics of the gas film. It can change the coupling relationship between the natural frequencies of the system and the whirl frequencies of the gas film. For hybrid gas bearings, the tangential angle between 55° - 60° , both to ensure the gas film have greater stiffness, while also have a more reasonable damping characteristics, to ensure the bearing operated high-speed and smoothly.
