

Enhanced Bandwidth Nonlinear Resonance Electromagnetic Human Motion Energy Harvester Using Magnetic-Springs and Ferrofluid

Chunfang Li, Shuai Wu, P. C. K. Luk, Min Gu, and Zongxia Jiao

Abstract—An enhanced bandwidth nonlinear resonant electromagnetic energy harvester has been designed to harness low frequency energy from basic human motion. Some vertical stacked cylindrical permanent magnets (PMs) constitute the inertial mass of the proposed harvester, which is suspended axially by two magnetic-springs and circumferentially by ferrofluid within a carbon fiber tube. In order to widen the frequency band and improve harvesting efficiency, two PMs are respectively fixed on the two end caps of the carbon fiber tube, so as to form two magnetic-springs with variable stiffness by cooperating with the PM stack. The self-assembled ferrofluid around the PM stack acts as its bearing system to minimize any friction during its movement. Copper wire are wrapped outside the tube to form the armature winding. The stiffness characteristic of the magnetic-springs and the optimum equilibrium position and number of windings have been determined by finite element method (FEM) analysis. As a proof of concept, a portable prototype of the proposed energy harvester that weighs 110g and with a volume of only 37.7cm³ is fabricated. A series of experiments are carried out and the results show that the frequency band of the harvester becomes wider as the external vibration intensity increases. In addition, the effectiveness of ferrofluid in reducing friction is demonstrated under walking and running conditions. Without ferrofluid, the maximum average outputs are 10.15mW and 32.53mW respectively for walking and running. With ferrofluid, the maximum outputs are 17.72mW and 54.61mW, representing an increase of 74.58% and 67.88%, respectively. Furthermore, the prototype exhibits an average power density of 1.45mW/cm³ during running motions, which compares favorably with existing harvesters used in low power wearable devices.

Index Terms—Nonlinear resonance, vibration energy harvester, human motion, magnetic-spring, ferrofluid

I. INTRODUCTION

WITH the development of technology, portable and wearable electronic devices are gradually reaching into people's lives, such as mobile phones, smart watches and wearable cameras. The energy supply for these portable and wearable electronic devices comes mainly from batteries. Despite great advances in battery technology, battery capacity

is still a feature that limits the long-term working. On the other hand, charging these portable and wearable devices under some conditions, e.g. long time field, is inconvenient or impossible. Indeed, human motion contains sufficient energy for these devices. Therefore, it is of great significance to develop a small energy harvester which can harvesting human motion energy and charging the battery continuously. And this idea has attracted a lot of research interesting recently. In general, the harvesting of human motion energy is achieved through various transfer mechanisms such as piezoelectric [1]–[3], electrostatic [4]–[6], electromagnetic [7]–[15], and hybrid [16], [17], which convert human motion energy into electrical energy [18]. However, the piezoelectric energy harvesters has a disadvantage of low generation efficiency in low frequency and electrostatic energy harvesters require very high processing technologies. Therefore, the electromagnetic mechanism is chosen in this study because of the simple mechanical structure, suitable for low frequency motion and low cost.

The electromagnetic harvester usually using a resonance vibrator to generate electrical power [19]. For human motion, such as ankle swing and heel landing during walking and running, vibrations are generated that are mainly composed of frequencies of $\leq 10\text{Hz}$ [20]–[22]. Therefore, energy harvesters that designed based on a specific resonant frequency appear to be less practical in vibration applications with a wide frequency range. In recent years, the use of various methods to broaden the harvestable frequency bandwidth of energy harvesters has extensively been reported as an alternative [23]–[27]. For example, Wei et al. [28] achieves a nonlinear resonant frequency by adjusting a magnetic-spring and the mass of the moving stack. Our group has been developed some human body energy harvesters designed by electromagnetic resonance to improve energy harvesting efficiency by using 3-dimensional resonance [29]. Additionally, the mechanical damping is a great challenge to design this type of small wearable electromagnetic energy harvesters, where friction is one of the important factors that results in their low power output. Therefore, new and innovative design solutions are needed to improve the performance of electromagnetic harvesters.

In the present study, a enhanced bandwidth nonlinear resonance electromagnetic energy harvester using magnetic-springs and ferrofluid is proposed to harvest energy from human motion. The vibrator of the proposed harvester is a PM stack which has several PM rings are placed in opposing

that is excited by external motion. The dynamic model of the motion can be expressed as [31], [32]:

$$m\ddot{z}(t) + (c_m + c_e)\dot{z}(t) + F_r(t) = m\ddot{y}(t) \quad (2)$$

where m is the mass of PM stack, the absolute displacement of PM stack and the frame are $x(t)$ and $y(t)$, respectively, the relative displacement of the PM stack can be got by $z(t) = x(t) - y(t)$, F_r is the nonlinear repulsive force of the moving magnetic stack, c_m is the mechanical damping coefficient and c_e is the electrical damping coefficient.

Fig. 2: Schematic diagram of energy harvester model

The initial distance (l_0) between the end PM and PM stack is a key parameter in determining the stiffness of the magnetic-spring. In this study, this distance is optimized by the FEA simulation and dynamic simulation. The repulsive force F_r of the magnetic-spring has a nonlinear relationship with the relative distance z , which can be expressed as [28]

$$F_r = k_1 z + k_2 z^3 \quad (3)$$

where k_1 and k_2 are polynomial coefficients of the repulsive force. It is a typical periodically forced oscillator with the nonlinear elasticity, which can be written as

$$\ddot{z} + 2\xi\omega_n\dot{z} + \omega_n^2 z + \beta z^3 = F \cos(\omega t) \quad (4)$$

where $2\xi\omega_n = c/m$, $c = c_e + c_m$, $\omega_n^2 = k_1/m$, $\beta = k_2/m$, $F = -\omega^2 A$.

It is usually called a duffing oscillator which has more complex potential than in simple harmonic motion. For a certain range of parameters in the Eq. 4, the frequency response may no longer be a single-valued function of forcing frequency ω . Since magnetic-spring is like a hardening spring ($k_1 > 0$ and $k_2 > 0$), the frequency response will hang to the high frequency side.

The FEA simulation results of F_r with $l_0 = 15, 17, 19\text{mm}$ are shown in Fig. 3a. And the value of k_1 and k_2 under different l_0 are also obtained by polynomial fitting. Thus the coefficients of k_1 and k_2 are lie on l_0 . The frequency response with different l_0 is obtained by dynamic simulation is shown in Fig. 3b. The Gray area is the expected frequency range 0–6Hz and the amplitude z is 6mm. As can be seen in Fig. 3b, when $l_0 = 17\text{mm}$, it can best meet the frequency range of human motion, so that the output power generated by the harvester

(a) Nonlinear repulsive force.

(b) Frequency response of the relative displacement

Fig. 3: The dynamic simulation results of harvester

is the maximum. Therefore, the $l_0 = 17\text{mm}$ is selected in the present study.

B. Magnetic field simulation and windings design

To achieve maximum output power, windings also needs to be optimized based on the magnetic field of the PM stack. The most important parameters of a winding include the diameter of the enameled wire (d_c), the number of winding layer (n) and the length of a winding (L_{coil}). These three parameters decide the total length and resistance of the enameled wire used. The total length of the enameled wire (l) can be calculated as

$$l = 3 \sum_{i=1}^n \frac{L_{\text{coil}}}{d_c} 2\pi(0.5D_{\text{to}} + (n - 0.5)d_c) \quad (5)$$

And the resistance of windings can be calculated as

$$R = \rho \frac{l}{s} = \rho \frac{4l}{d_c^2} \quad (6)$$

where R is the resistance of windings, ρ is the coefficient of enameled wire. The resistance of windings should match to the load impedance which should be decided with the magnetic field distribution.

The magnetic field distribution of PM stack is analyzed by FEM analysis. The simulation model and results are illustrated in Fig. 4. The ferrofluid does not considered in this FEM simulation since it is very easy saturated and have little effect

on filed density. The simulation model is established based on the design parameters, the total height of PM stack is 38mm. The center radius of each layer in the winding also are marked with $r = 10.15\text{mm}$, $r = 10.45\text{mm}$, $r = 10.75\text{mm}$ and $r = 11.05\text{mm}$, respectively. As can be seen in Fig. 4, the magnetic flux lines between two magnets are guided by a pole piece that allows the flux lines to interact with the windings along the radial direction as best as possible, increasing the power output. Additionally, the magnetic flux density becomes smaller as the center radius r of each layer increases.

The magnetic flux density in radial direction Mag_Br at different locations are shown in Fig. 5, where the horizontal axis represents the height of the PM stack. Fig. 5 shows that Mag_Br gets a maximum value in the gray range, where the gray ranges are the installation positions of iron pole pieces. Deviation from the gray range causes Mag_Br to decrease, and drop to 0T at some certain positions. Therefore, the maximum voltage can be generated from a winding when the winding corresponds to the position of the pole pieces. For purpose of high output power, three windings are wound at positions corresponding to three pole pieces when the vibrator is at its equilibrium position. Of course, these positions are the optimum equilibrium positions of windings. Fig. 5 also exhibits Mag_Br at different values of r , and Mag_Br decreases as r grows.

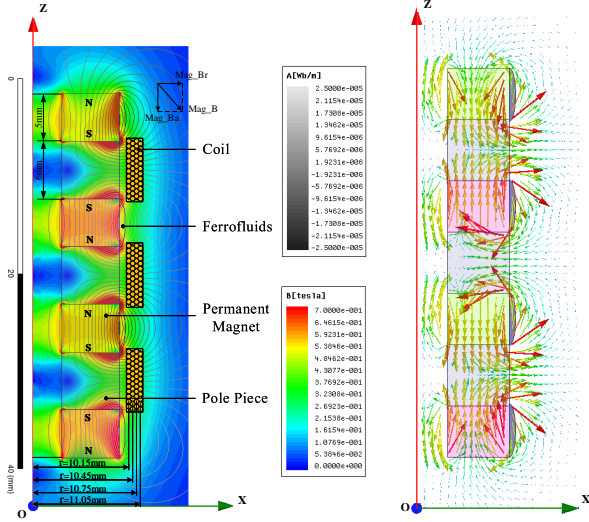

Fig. 4: The magnetic flux density distribution of PM stack

Then the winding parameters can be decided. In the present study, the load impedance is 4Ω . $L_{\text{coil}} = 6\text{mm}$ is set for cover the maximum flux density range. The diameter of enameled wire and winding layer can be optimized by Eq. 5 and 6. $d_c = 0.3\text{mm}$ and 4 layer is chosen in the present study.

IV. PROTOTYPE AND EXPERIMENT

A. Prototype and Test Rig

The prototype of the proposed variable resonance electro-magnetic energy harvester is fabricated and the entire test rig is shown in Fig. 6. The carbon fiber tube was chosen in this prototype because of its advantages of high structural strength,

Fig. 5: Magnetic flux densities in radial direction of different radius

corrosion resistance and light weight. The PM stack, which works as a proof mass, consists of four NdFe35 Magnets and three carbon steel hollow blocks. PM stack is suspended in the axial direction by the repulsive forces between PM stack and two magnets fixed at both ends of the carbon fiber tube. In the circumferential direction, PM stack is ‘wrapped’ by ferrofluid. The role of ferrofluid is to keep the PM stack away from the inner wall of carbon fiber tube, reducing the friction of PM stack during the movement. It is expected that the design resistance of the proposed energy harvester is about 4Ω to match an energy storage circuit being designed. The energy storage circuit will not be discussed in this paper. According to simulation results and actual requirements, it is decided that three windings made of 0.3mm enamelled wire are wrapped around the outside of the carbon fiber tube at the optimum equilibrium positions of windings. As the number of winding layers increase, the increase in voltage generated by this winding may be less than the increase in the resistance of the winding, which in turn reduced the output power of the proposed harvester. Therefore, Each winding is made with 4 layers, measuring the resistance of each winding is 1.3Ω , and the total resistance of the prototype is $3 \times 1.3\Omega = 3.9\Omega$. After detecting and comparing the waveforms of the generated voltage from the three windings, they are then connected in series to achieve the maximum energy output. The full geometric parameters are also presented in Table. II.

The test rig mainly consists of a voice coil motor (LA30-48-000A, BEI), a data acquisition module (NI USB-4431), a brush type PWM servo amplifier (AMC) and two computer. It is also clearly observed that the glistening ferrofluid covered the surface of PMs in Fig. 6, especially the edge of PM, where magnetic field density is the greatest.

B. Experimental Results and Discussion

In order to measure the effective frequency band of the prototype, the open circuit vibration test is carried out. The voice coil motor is driven to provide the required excitation frequency and different acceleration levels. The output voltage of prototype is obtained by the data acquisition module. The open circuit output voltages of the proposed energy

Total Mass of the harvester	M	110g
Total Length of the harvester	L_{EH}	120mm

harvester at different excitation levels and different excitation frequencies are collected. The waveforms of the output voltage under different excitation conditions are shown in Fig. 7a, where the acceleration levels are set to 0.16g, 0.20g and 0.25g, the excitation frequency is set to 1Hz, 2Hz, 3Hz, ..., 10Hz, and each excitation condition is applied for 2s. As can be seen in Fig. 7a, the output voltage generated by the prototype increases as the acceleration level increases at each excitation frequency. For an acceleration level of 0.16g, the generated maximum voltage is about 2V at 6Hz. For a large acceleration of 0.20g, the voltages generated at the three excitation frequencies of 6Hz, 7Hz and 8Hz are relatively higher. At an acceleration level of 0.25g, a maximum voltage of 5V is achieved at a frequency of 9 Hz. Fig. 7b shows the RMS voltage of different excitation conditions. It can be found that the effective bandwidth of the harvester becomes wider when the acceleration level increases. Therefore, the voltage response and the effective bandwidth exhibit an increasing trend with the increasing excitation levels, thanks to the nonlinear magnetic-spring.

Then, the output performance of the proposed harvester is evaluated from basic human motions including walking and running by fixing the harvester near to an ankle. The open circuit instantaneous voltage waveforms and frequency spectrum during walking and running are shown Fig. 8 and Fig. 9, respectively. The frequency of walking motion is about 1Hz, and running frequency is roughly 1.43Hz. As can be seen in these two figures, the instantaneous voltage generated by running is higher than the walking. Compared with the

presence and absence of the ferrofluid experiments in the same motion mode, it is found that the voltage amplitude decay is slowed down after adding ferrofluid. And the sound generated by the friction between the PM stack and the carbon fiber inner wall also is weakened during the experiment. Therefore, it can be inferred that the ferrofluid plays an important role in reducing friction.

Fig. 10 shows the output RMS voltage and average power delivered to load R_o range of from 1Ω to 10Ω by the prototype during the same walking and running style as above. As can be seen from these average power curves, the maximum output power corresponded to a load of 4Ω . Additionally, it is noteworthy that more energy can be generated during running motion than walking motion. For walking motion, the value of RMS voltage delivered to the optimum load of 4Ω is 0.22V without ferrofluid, while the use of ferrofluid increases by 0.29V. According to $\bar{P} = V_{rms}^2/R_o$ calculates the average power in both cases are 10.15mW and 17.72mW, respectively. Where V_{rms} is the RMS voltage across the corresponding load resistance R_o . And The latter relative to the former increases by around 74.58%. For running motion, the output maximum average power of using ferrofluid are 54.61mW from the experimentally obtained results, which is about 67.88% higher than the case where ferrofluid are not used. In summary, ferrofluid are indeed beneficial to improve the output power.

Table. III shows a summary of the proposed harvester and the previously reported electromagnetic energy harvester. The designed harvester has a small volume, a simple structure, a low manufacturing cost and convenient carrying, but it still needs to be further improved in power generation capacity.

V. CONCLUSIONS

An nonlinear resonance electromagnetic energy harvester using magnetic-springs and ferrofluid for suspension is presented in the present study. This energy harvester is designed to scavenge energy from human motions to supply power for wearable devices. This harvester adopts two magnetic-springs with a stiffness varying with vibration displacement to widen the frequency band, thereby increasing the generated energy. Additionally, ferrofluid reduces the friction of the proposed energy harvester and makes it highly efficient in producing electrical power. The characteristics of magnetic-spring, the optimum equilibrium position of windings and number of windings also are determined by FEM analysis in Ansoft Maxwell. The prototype of the proposed energy harvester that weighs 110g and with a volume of only $37.7cm^3$ has been fabricated, and a range of experiments are carried out to characterize the proposed harvester. The experimental results of the open circuit frequency response show that the frequency band of the harvester widens as excitation intensity increases. Furthermore, the effectiveness of the ferrofluid in reducing friction is demonstrated under walking and running conditions. Two maximum average output power of 17.72mW and 54.61mW are obtained by the proposed energy harvester of using ferrofluid from walking and running. Compared to the case of the absence of ferrofluid, the outputs are increased by 74.58% and 67.88%, respectively. In the future work, the size

She is currently studying for a master's degree in the School of Automation Science and Electrical Engineering at Beihang University. Her research interests include mechatronics, modeling and simulation.

Shuai Wu ShuaiWu (M'15) received the Ph.D. degree in mechatronics engineering from Beihang University, Beijing, China, in 2011. He was with Beihang University, Beijing, China, as a Postdoctoral Fellow from 2011 to 2013 and has been a Lecturer there since 2013. His research interests include hydraulic servo control of aircraft, modeling and simulation, dynamics and control of mechatronic systems, and advanced electrical, and hydraulic servo components.

Patrick Chi-Kwong Luk Patrick Chi-Kwong Luk (SM10) was born in Hong Kong. He received the High Diploma degree with merits from Hong Kong Polytechnic University (PolyU), Hung Hom, Hong Kong, in 1983, the M.Phil. degree from Sheffield University, Sheffield, U.K., in 1989, and the Ph.D. degree from the University of South Wales, Newport, U.K., in 1992, all in electrical engineering. He started his career in industry as an Engineer Trainee between 1981 and 1983 at GEC (H.K.) and then after graduation as an Applications Engineer at Polytek Engineering Co. (H.K.). In 1986, he was a Senior Researcher in the Industrial Centre at PolyU. Beginning in 1988, he held academic positions at the University of South Wales, Robert Gordon University, U.K., and the University of Hertfordshire, U.K. He joined Cranfield University, Cranfield, U.K., in 2002, where he is a Chair Professor in electrical engineering. His current research interests include electrical drives, renewable energy conversion. He has authored over 170

Min Gu Min Gu was born in Inner Mongolia, China in 1993. She received a bachelor's degree from the Department of Mechanical Engineering, Nanjing University of Aeronautics and Astronautics, in 2016. She is currently studying for a master's degree in the School of Automation Science and Electrical Engineering at Beihang University. Her research interests include mechatronics, modeling and simulation.

Zongxia Jiao Zongxiao Jiao (M'11-SM'13) received the B.S and Ph.D degrees from Zhejiang University, Hangzhou, China, in 1985 and 1991, respectively. He was with Beihang University, Beijing, China, as a Postdoctoral Fellow from 1991 to 1993 and has been a Professor there since 1994. He is currently the Dean of the School of Automation Science and Electrical Engineering, Beihang University. His research interests include actuators, sensors, fluid power and more electrical aircraft. Prof. Jiao was recipient of the Changjiang Scholar Professor in 2006 and the Distinguished Young Scholar of China in 2008.

Enhanced bandwidth nonlinear resonance electromagnetic human motion energy harvester using magnetic-springs and ferrofluid
