**INCENTIVES AND MANAGERIAL
EXPERIENCE IN MULTI-TASK TEAMS:
EVIDENCE FROM WITHIN A FIRM**

Abstract

This paper exploits a quasi-experimental setting to estimate the impact that a multi-dimensional group incentive scheme had on branch performance in a large distribution firm. The scheme, which is based on the Balanced Scorecard, was implemented in all branches in one division, but not in another. Branches from the second division are used as a control group. Our results suggest that the balanced scorecard had some impact, but that it varied with branch characteristics, and in particular, branches with more experienced managers were better able to respond to the new incentives.

Keywords: incentive design, balanced scorecard, managerial experience

Acknowledgements

1. Introduction

Many organisations provide some form of incentive pay to managers and workers. What form should these incentives take? This is the topic of many papers in the economic and management literatures. A well known theoretical result suggests that workers should not be made jointly responsible for single tasks, because sharing responsibility increases the total risk that each worker faces of successfully completing the task without increasing the benefit (Holmstrom and Milgrom, 1991). Holmstrom and Milgrom also suggest that tasks should be grouped together, based on the cost of measuring and rewarding performance in that dimension. Some workers should do the easy-to-measure tasks, and their pay should be contingent on performance, while other workers should focus on hard to measure tasks and receive fixed wages. This is because if a worker has both easy and hard to measure tasks they will concentrate on the easy to measure tasks, as the expense of the hard to measure tasks.

However, one of the most widely used incentives schemes - the Balanced Scorecard - runs counter to these results. The Balanced Scorecard was introduced by Kaplan and Norton (1992), and variants of it have been adopted by a large number of firms and organisations across the globe.¹ The idea behind the Balanced Scorecard is that managers can improve performance by monitoring and rewarding a large range of linked activities (usually 15-20 covering four different dimensions – financial, customer, internal and innovation/learning). These activities are designed to reflect both current actions that are assumed to impact future performance, as well as the outcomes of past actions. Performance is typically evaluated at the group level (for example, business unit, branch or team) and incentive payments are often based on group performance versus all of the indicators. Thus as well as forming the basis for an incentive scheme, the Balanced Scorecard also provides information to managers and workers: *“The Balanced Scorecard is like the dials in an airplane cockpit: it gives managers complex information at a glance.”* (Kaplan and Norton, 1991, p71)

As well as running counter to results from the economics literature, the use and effectiveness of the Balanced Scorecard has been criticised in the management

literature.² Some of the assumptions of causality that underpin the designed of balanced scorecards are challenged (Nørreklit, 2000; Nørreklit, 2003). Ittner et al. (1998) present a compelling case illustrating the difficulty of basing an incentive scheme on a balanced scorecard. While Jensen (1991) argues that the Balanced Scorecard will do nothing to solve the agency problem. It provides no information on how managers and workers should trade off different objectives, so will fail as an incentive mechanism, although he accepts that it may provide useful information to managers on the company's strategy and drivers of value.

With all these arguments against the Balanced Scorecard why have so many firms adopted it? Has it been an effective incentive scheme? Does it provide useful information to managers? The rapid uptake of the Balanced Scorecard has been largely fuelled by high profile success stories in other firms, yet there is little empirical evidence on how well the scheme works.³

In this paper we exploit a quasi-experimental setting within a single firm in order to investigate the effectiveness of the Balanced Scorecard. The firm implemented the Balanced Scorecard in one division to see how well it would work before rolling it out across the firm. This allows us to overcome one of the main problems in evaluating incentive schemes – the fact that who adopts the incentive mechanisms is endogenous – by comparing monthly performance across a large number of branches in two different divisions.⁴

Another advantage of our setting is that the firm initially used profit related pay in all divisions. This means that we are able to identify the impact of the particular form of incentive scheme, rather than conflate the impact of any form of incentive pay with this particular form of incentive pay. We also investigate the idea that it was not the incentive aspect of the Balanced Scorecard that was influential, but that it improved the information that was transmitted to managers and workers and this helped them to focus their actions on more profitable margins.

We find that the Balanced Scorecard changed behaviour, but that overall this change did not lead to increased profits in all the branches where it was implemented – in some cases costs increased by at least as much as sales. However, the impact varied across branches – branches with more experienced managers were able to effectively

³ Hoque and James (2000) survey 66 Australian manufacturing firms, Banker, Potter and Srinivisan (2000) look at 18 hotels, Malina and Selto (2001) consider multiple divisions of a large firm, Ittner, Larcker and Meyer (2003) conduct a case study in a large firm, Neely, Martinez and Kennerly (2004) consider 35 branches in one firm, Davis and Albright (2004) look at nine branches of a firm, Burgess et al (2004) evaluate a randomised trial incentive scheme in Job Centres in the UK.

⁴ Burgess et al (2004) are able to evaluate the introduction of a team based multi-task incentive scheme in Job Centres in the UK, where implementation was randomised.

improve performance, while less experienced managers were not able to effectively improve performance. We use interviews with a number of individual managers to explore the idea that the impact of experience enabled managers to better interpret the large number of indicators and to effectively allocate effort within the branch.

The idea is that it is not only the incentives that matter, but also the ability of managers and workers to respond to them. When it is necessary for managers and workers to perform a large number of tasks (for example, the tasks involved in running a retail establishment), it is important that the manager can effectively decide where best to put both his and workers' marginal effort. The Balanced Scorecard gives the manager additional information on past performance, but does not tell the manager where additional marginal effort will be most effective. It gives the same incentive to all measures. This has been one of the main features that has been criticised (Jensen, 2001), that the Balanced Scorecard does not tell managers where marginal effort will be the most effective in improving performance. We interpret the fact that more experienced managers were able to achieve better performance under the Balanced Scorecard as showing that it requires additional ability (acquired through experience) for the manager to know where the greatest pay off will be. We corroborate this interpretation in interviews with a large number of branch managers.

The structure of the rest of the paper is as follows. In the next section we describe the firm, the Balanced Scorecard, how it was implemented and the impact we would expect to find. Section 3 describes the data and our empirical approach. Section 4 presents the results. A final section summarises and concludes.

2. The Setting

We describe the firm, the incentive scheme, how it was design and implemented, and then discuss what impact we expect to see on performance.

2.1 The firm

The firm is a multinational distributor of heating and plumbing products (see Figure 1). It has thousands of branches in over ten European and North American countries and employs around 50,000 people. In the UK there are four main divisions. Both divisions have several sub-divisions, or brands. We use data on the largest brand in the two largest divisions. Each brand is made up of a large number of branches. During the period we consider branches dealt primarily with one brand, and acted as relatively small trading units, employing between 2 and 32 staff (with a mean of 10).

Figure 1: Firm Structure

We compare performance in the dominant brand in Division 1 (where the Balanced Scorecard was introduced) with the dominant brand in Division 2. Prior to August 2002 both divisions used the same incentive scheme, which was based only on branch profits. Division 2 kept this scheme after August 2002. The two divisions are similar in terms of average sales and profits per branch. They differ in that they sell distinct product (which are both used in building). Another distinction is that the average value of and margin earned on the product sold in Division 2 is higher. However, the branches operate in similar economic conditions, for example, they employ people from the same labour markets, and experience similar demand shocks.

The dominant component of firm profits is individual branch profits, though there are also orders received at head office and volume discounts that head office receives from suppliers (called rebates). In this study we focus on branch profits. Profits of an individual branch are the revenue earned on the sale of each product, minus the costs of sale, minus central branch costs. The main elements of cost at the branch level are the cost of goods sold, labour costs, infrastructure (including capital costs), distribution and transport costs. Other costs include general and administration costs, spending on information technology, local marketing, advertising and other branch level administrative costs. These are described further in the data section below.

Effort of branch staff and branch managers can affect outcomes in the following ways:

- the price paid for a product can vary with each transaction (branch staff have discretion to negotiate individual prices, starting from a base price);
- staff deal directly with customers and thus have influence on the quantity, type and range of products sold;

- branch (as well as regional) managers influence the quantity sold through setting base price levels, marketing and setting special offers;
- staff and branch (as well as regional) managers' actions can affect hiring and firing costs (through staff retention levels), volume discounts (through the type and quantity of goods sold) and various other branch level costs in a number of ways.

A typical branch is managed by a branch manager,⁵ and has an administrator who works in the office, two or three sales staff, a driver, and three or four people who work in the warehouse or stockyard. Further details are given in Table A.1 in the Data Appendix. The role of the manager, among other things, is to decide on hiring decision (in conjunction with head office), allocate staff to tasks, decide on special offers and decide on the level and type of local marketing activity.

2.2 The incentive scheme

Prior to August 2002 employees in both divisions received a bonus that was a function of branch level profits. The bonus was allocated to branches based on a percentage of their profits, and was allocated to branch staff by the branch manager, at his discretion and in consultation with the regional manager.

Senior management became concerned that the profit-based bonus scheme was leading to dysfunctional behaviours, as is emphasised in the literature.⁶ For example, managers had incentives to adjust the timing of capital investment where they would affect bonus payments, and they faced incentives to compete for business with other local branches, because profits were calculated on a point of sale basis. The firm was also concerned that branch staff were not putting sufficient effort into activities that enhanced long-run profitability, such as maintaining customer loyalty and relationships with suppliers. Senior management decided to change the basis of the performance measurement and incentive scheme in the organisation. They decided to trial a new scheme, based on the Balanced Scorecard, in Division 1 prior to rolling it out across the firm. The Balanced Scorecard was designed to overcome the dual problems of subjective performance evaluation (which can give rise to various forms of bias and encourage workers to waste effort to curry favour with managers) and focussing on one key performance target (which can lead to dysfunctional behaviour

---

⁵ The branch manager reports to a regional manager who reports to a brand operations director, who reports to a brand managing director who reports to a divisional managing director, who reports to the board.

⁶ See, inter alia, review by Prendergast (1999) and Hayes and Abernathy (1980).

with workers focusing all their energy on tasks that are rewarded, and ignoring those that are not included in the incentive scheme).⁷

The new incentives scheme made three big changes (i) it used multiple targets rather than a single target, (ii) it was non-discretionary rather than discretionary, (iii) it provided more information to managers on a wide range of indicators, such as customer behaviour and efficiency, then was previously available.

The specific incentive scheme that the firm implemented works as follows. The firm identified 17 key indicators of performance, including both financial and non-financial indicators of performance. Incentives were paid to each employee on a six-monthly basis, but effectively earned on a monthly basis. For branch staff and branch managers the payment was based on the number of points the branch earned in the month times the value of a point.⁸ Each branch is graded “green”, “amber” or “red” on each of the 17 measures contained in the balanced scorecard. A green grade earns 3 points, an amber grade 1.5 points and a red grade 0 points. The total number of points earned by the branch is given by,

$$\text{points} = (3 \times \text{green} + 1.5 \times \text{amber}) \times \text{number of people in branch.}$$

There are 17 measures in total so the maximum number of points per employee a branch can earn in a month is 51. In 2003 a point was worth £1 for branch staff (the value of a point is higher for managers) so the maximum bonus a branch worker could earn in a month was £51, or £612 a year. The average salary of branch workers is around £12,000, so the maximum bonus represents 5.1% of their salary.

The total amount the firm allocated for the scheme was £1,836,000. This was set aside in a separate account to signal the firm’s commitment to the scheme. The previous scheme, based on profits, cost about the same total amount.⁹ As well as changing the incentive structure, an important aspect of the Balanced Scorecard was the provision of more detailed information on performance, and crucially on several leading indicators of profitability. Each branch manager received a detailed report every month on the 17 measures.

Why did the firm implement the Balanced Scorecard in Division 1 and not Division 2? This is an important question, as our strategy for identifying the impact of the Balanced Scorecard relies on performance being independent of this decision. The

---

⁷ See Argyris (1952), Ridgway (1956), Holmstrom and Milgrom (1991), Kerr (1995) and for a recent review of the literature Prendergast (1999).

⁸ For regional managers it is based on the average of the points earned in branches under their control. For central office staff it is calculated based on a simplified version of the balanced scorecard containing only measures that the central office staff could affect.

⁹ The firm estimates the cost of implementation at around £0.5m, including the direct and indirect costs such as management time.

pragmatic reason is simply that the Divisions were run relatively independently and the Managing Director of Division 1 was rather more keen on management innovation, and particularly the Balanced Scorecard. At the outset the organisation considered whether it would subsequently implement the Balanced Scorecard in other divisions, but in essence decided to delay a decision and instead treat Division 1's implementation as a pilot study. Thus, we argue that the introduction can be treated as independent of any expectations about the impact the Balanced Scorecard would have in one Division over the other.

2.3 The design and implementation process

In evaluating the impact of the Balanced Scorecard we need to be careful to distinguish two questions - (i) did the new incentive scheme change behaviour, and (ii) did this behaviour lead to improved performance. The idea behind the Balanced Scorecard is that the firm needs to determine what are the key drivers of future profitability and build these into the incentive scheme.

The board devoted significant time to discussing what were the objectives for the division, what behaviours they wanted to encourage in the branch network, and how these behaviours might be reinforced through the choice and design of appropriate performance measures. At various stages during the process the directors consulted regional and branch managers. The firm invested considerably in education and training, as well as engagement with workers at all levels throughout this time.¹⁰ In the end the firm adopted 17 measures, shown in Figure 2 and described further in Tables 1.¹¹

Following a 9 month design and deployment process the Balanced Scorecard was introduced in business from 1st August 2002. The business' financial year ran from 1st August-31st July and the scheme was operated for the time period 1st August 2002-31st December 2005. For the purposes of this evaluation we will focus on two financial years 1st August 2002-31st July 2003 and 1st August 2003-31st July 2004.

---

¹⁰ The discussions were about what the objectives of the division were and who had control over them. Meetings were held in every branch and discussion was in depth and focussed on what individual workers could do to improve performance.

¹¹ Personal development was included as a measure, but the data were not adequately collected, so it was not used. The employee satisfaction survey had a low response rate (e.g 32% in December 2002), but the firm used it anyway.

Figure 2: The Scorecard Measures

2.4 Anticipated impact on performance

How do we expect the three key changes - (i) introduction of multiple measures, (ii) move from discretionary to non-discretionary, and (iii) increased information to affect performance? Remember that, as mentioned above, there was no major change in the overall value of incentives, just in their form.

In order to consider how it would affect performance we consider the incentives that individuals faced and how they changes. We assume that individuals seek to maximise their income, net of effort. Income consists of a base wage and an incentive payment, which is a function of performance. Performance is a function of the effort of all staff, managers and directors. Effort is costly. Individuals will exert effort up to the point where the marginal cost of effort equals the marginal benefit, in terms of the incentive payment. This is true under either scheme. What changed is the way performance is measured and rewarded.

Table 1: Balanced Scorecard Measures

<u>Financial measures</u>	
Return on Capital Employed	$[PBIT / (Debtors + Stock + Fixed Assets)] \times 100$
Growth in Profit	$[(Contribution\ This\ Year\ To\ Date - Contribution\ Last\ Year\ To\ Date) / Contribution\ Last\ Year\ To\ Date] \times 100$
PBIT as a % of Sales	$(Contribution\ YTD / Sales\ YTD) \times 100$
Positive Cash Flow	$[(Contribution - (+/-\ Stock\ Movement\ £'s) + (+/-\ Debtors\ Movement\ £'s) = Basic\ Cash\ Flow) / Total\ Sales] \times 100$
Sales Growth	$[(Sales\ PWD\ This\ Year\ To\ Date - Sales\ PWD\ Last\ Year\ To\ Date) / Sales\ PWD\ Last\ Year\ To\ Date] \times 100$
<u>Customer measures</u>	
Customer Satisfaction ^b	Score achieved via an external survey
Customer Retention	$[(No.\ of\ Customers\ retained\ in\ rolling\ 12\ months\ to\ current\ month - No.\ of\ Customer\ retained\ in\ rolling\ 12\ months\ to\ last\ month) / No.\ of\ Customers\ retained\ in\ rolling\ 12\ months\ to\ last\ month] \times 100$
Sales Mix	$[(Sales\ of\ Selected\ SPGs\ This\ Year\ to\ Date - Sales\ of\ Selected\ SPGs\ Last\ Year\ to\ Date) / Sales\ of\ Selected\ LLSPGs\ Last\ Year\ to\ Date] \times 100$
Availability of Stock Range	$(Sum\ of\ Number\ of\ Days\ where\ Stock\ Ins\ for\ your\ MBR\ are\ equal\ to\ or\ greater\ than\ 90\% / Number\ of\ Trading\ Days) \times 100$
<u>Internal measures</u>	
Operational Efficiency	Stock/Debtors/Labour/Transport – Yes/No against individual targets: Stock 40 days, Debtors 0.5% against Sales, Labour 10% against Ex-Stock Sales, Transport 8% against Delivered Sales, where 25% is awarded per point
Operational Standards	$(Score\ from\ Operational\ Standards\ Check\ List / Total\ possible\ score\ from\ Operational\ Standards) \times 100$
Inter-company Co-operation	$[(Number\ of\ Customers\ trading\ with\ foreign\ Branches\ This\ YTD - Number\ of\ Customers\ trading\ with\ foreign\ Branches\ Last\ YTD) / Number\ of\ Customers\ trading\ with\ foreign\ Branches\ LYTD] \times 100$
<u>People measures</u>	
Staff retention	$(Number\ of\ voluntary\ leavers\ on\ a\ rolling\ 12\ month\ basis / Average\ head\ count\ in\ rolling\ 12\ months) \times 100$
Employee satisfaction	$(The\ number\ of\ people\ who\ indicate\ they\ are\ satisfied\ at\ work / average\ number\ of\ employees\ over\ the\ period) \times 100$
Communication	$(Number\ of\ people\ who\ feel\ they\ have\ been\ made\ aware\ of\ businesses\ activities / Average\ number\ of\ employees\ over\ the\ period) \times 100\ (By\ Region)$
<u>Supplier measures</u>	
Spend with Approved Suppliers	$(Purchases\ from\ preferred\ Suppliers\ This\ Year\ To\ Date / Total\ purchases\ from\ Suppliers\ This\ Year\ To\ Date) \times 100$

The main objectives of the firm were to encourage workers to put more effort into a broad range of activities that were previously not rewarded, but which the directors of the firm believed feed into long-term profits (long term being over several months to one to two years). The tasks concerned are substitutes from the individual workers point of view (they each take time and an individual worker can spend time on one task or another), but from the point of view of the firm and value-maximisation they are complements, in the sense that workers need to spend time on all of the tasks in order to maximise the value of the firm. For example, a worker can either sweep the floor or restock the shelves - from the workers point of view these are substitute activities. But from a customer's point of view these are complementary characteristics of a shop - they want both a clean shop and well stocked shelves.

Where workers undertake tasks that are substitutes for each other, and where the rewards are equal and independent (as is the case here), then workers will devote more time to those tasks they find easiest. If the measurement of some tasks is more precise, or more clearly understood – in the sense that it is easier to identify improvements in performance - then workers will devote more time to those tasks that are measured more precisely.¹² This is essentially the objection that Jensen (2001) and others have made to the Balanced Scorecard - it does not give clear guidance to workers as to what is the most important task to perform (should they spend another 10 minutes sweeping the floor, or should they start stocking the shelves), but rather allows them to put too much effort into non-profitable tasks (either because they have mis-information about the payoff to the individual tasks or because both are rewarded so they simply do the one that is easiest).

The Balance Scorecard scheme with 17 measures was complex, and managers were provided with large amounts of information. In order to effectively use this information the manager needed to be able to assimilate it and understand what it meant in terms of future profitability. A key issue is that the data as presented in the Balanced Scorecard was very aggregated, hence managers were not able to directly take action based on them. Each manager need to be able to translate the information provided on the Balanced Scorecard so that it told them something specific about the local situation. For example, consider one of the measures - customer retention. Each month the manager would be given information on how many customers they were retaining compared to the same time last year. This is a useful leading indicator of profitability. However, simply knowing that you retained 5% fewer customers than this time last year is not sufficient information to enable the manager or shop workers to be able to act on it. They needed to be able to figure out which customers were not coming back and why in order to know where to put effort in order to increase retention rates. This is where experience comes in. Our thesis is that experienced managers are either more likely to have seen in the past, or are better able now to develop, local solutions that allow them to take action to improve performance

---

¹² See Holmstrom and Milgrom (1991) and Burgess et al (2004).

according to the Balanced Scorecard. A more experienced manager will both be better able to interpret the large number of indicators, and better able to (e.g. more credible) motivate staff to put effort into the activities that matter for performance; with an inexperienced managers workers can easily become overloaded with information and tasks, leading to underperformance. We explore this idea in our empirical analysis below.

3. Data and econometric method

3.1 Data

The main data is drawn from the monthly Profit and Loss (P&L) accounts of the firm. We have information at the branch level on sales, gross profits (sales minus cost of goods sold), trading profits, labour costs, infrastructure, transport costs, general and administrative costs, information technology investment, local marketing and advertising expenditure and other costs. We have these data monthly from August 1999 to July 2005. We also have data on employees in each branch in Division 1 including their age, job title, and length of tenure in the firm from August 2003 to July 2004.

We use the location (postcode) of each branch to match branches from the two divisions. There are a number of factors that affect sales, but are both exogenous (not affected by actions of the firm) and will have a common effect across both divisions. These include the economic cycle, local economic and labour market conditions and other local factors. There may, however, be some variation in demand conditions. The products sold by division one are used both inside and outside, while those sold by division 2 are predominantly used inside. Thus weather conditions will have a differential affect on demand for the two goods. To control for this we use monthly data from twenty-six weather stations in the UK on the minimum temperature (in Celsius) and rain fall (in millimetres). In addition, goods sold by division 2 are used more intensively in refitting houses, while goods sold in division 1 are used more intensively in new buildings. To control for this we use data on total quarterly construction activity in a range of categories to capture variation in aggregate demand. These data come from the Construction Products Association. We aggregate separate information on aggregate quarterly output for new private sector housing, private and public sector remodelling and commercial and industrial development. The firm has given us the weight of each of these in demand for each of their brands, and we use this to construct a measure of quarterly aggregate demand for each brand.

Table 2: Mean (in £,000) and standard deviation for Division 1 branches and matched Division 2 branches

	Division 1 Brand A	Division 2 Brand C (matched only)
<i>Branches</i>	<i>156</i>	<i>121</i>
<i>Observations</i>	<i>11076</i>	<i>11076</i>
Sales	152.5 (87.8)	166.4 (103.4)
Gross profits	45.7 (28.3)	39.9 (19.1)
Trading profits	15.3 (19.4)	22.8 (15.6)
Labour costs	14.9 (7.7)	8.8 (4.2)
Infrastructure	7.6 (4.7)	4.5 (2.4)
Transport costs	4.2 (2.6)	1.1 (1.1)
General and administration	1.4 (1.3)	0.8 (0.6)
Other	0.9 (0.7)	0.7 (0.5)
IT	0.48 (0.22)	0.49 (0.13)
Marketing and advertising	0.15 (0.34)	0.02 (0.15)

Notes: Values are monthly in nominal £,000 over the period August 1999 to July 2005.

Tables 2 and 3 show descriptive statistics of the main variables. Tables 4 and 5 show descriptive statistics on the number of employees, types of jobs within a branch, and the average experience and age of staff.

Table 3: Descriptive statistics, weather and demand

	Mean (standard deviation)
Minimum temperature (in Celsius), measured at 26 points throughout the UK	7.28 (4.17)
Rain fall (in mm)	65.7 (41.0)
National quarterly demand for activities using Brand A products (in £m)	2628 (200)
National quarterly demand for activities using Brand products (in £m)	2588 (168)

Notes: Data on weather if from <http://www.met-office.gov.uk/climate/uk/stationdata/>

We match each branch from Division 1 brand A to the geographically nearest branch from Division 2 brand C. The markets for the goods sold by the firm are very local - the firm tells us that consumers are rarely willing to travel further than 30 kilometres. There are four Division 1 brand A branches which do not have a Division 2 brand C branch within 30 km, and we exclude these from our analysis. The average distance between matched branches is 4.5 kilometres.

3.2 Econometric Method

Our setting allows us to adopt a quasi-experimental design method¹³ and use a combination of matching and a difference-in-difference estimator. As highlighted above, a major problem in the literature that attempts to identify the impact of

¹³ See, inter alia, Cook and Campbell (1979) and Heckman, Ichimura and Todd (1997). For a recent survey see Blundell and Costa-Dias (2005).

incentive schemes has been the fact that organisations choose whether and which incentive schemes to adopt - the adoption of the incentives scheme is endogenous.

We are able to use the fact that the firm implemented the Balanced Scorecard in one part of the firm, but not the other, to tackle this problem. Differencing between the matched branches allows us to control for all of those factors that have a similar affect on the two branches. We control for the factors that affect the branches differently, such as the weather.

To see this, we can write the determinants of sales for each type of branch, where we denote branches within Division 1 Brand A with subscript i and within Division 2 Brand C with subscript j

$$(3) \quad \begin{aligned} S_{irt} &= \alpha_i + \beta_1 L_{rt} + \beta_2 D_{1t} + \beta_3 \tau_t + \beta_4 W_{rt} + \gamma BSC_t + e_{irt} \\ S_{jrt} &= \alpha_j + \lambda_1 L_{rt} + \lambda_2 D_{2t} + \lambda_3 \tau_t + \lambda_4 W_{rt} + \varepsilon_{jrt} \end{aligned}$$

where S: sales, L: local economic factors such as labour markets, supply chain, etc., D: national demand, τ : seasonal (monthly) dummies, W: weather, BSC: indicators of the use of the balanced scorecard, e, ε : idiosyncratic shocks.

We match each branch from brand A to the geographically nearest branch from brand C and consider the difference between the two braches. This takes the form

$$(4) \quad \begin{aligned} (S_{irt} - S_{jrt}) &= (\alpha_i - \alpha_j) + (\beta_1 - \lambda_1)L_{rt} + (\beta_2 D_{1t} - \lambda_2 D_{2t}) \\ &\quad + (\beta_3 - \lambda_3)\tau_t + (\beta_4 - \lambda_4)W_{rt} + \gamma BSC_t + (e_{irt} - \varepsilon_{jrt}). \end{aligned}$$

We have argued that $\beta_1 = \lambda_1$, i.e. local market conditions effect the two type of branches in the same way, so that they drop out of the difference equation, and that $\beta_2 = \lambda_2$, i.e. that changes in aggregate demand feed through into sales and profits in the same way, so that we can include the difference in aggregate demand for goods sold in the two branches. This gives:

$$(4') \quad \begin{aligned} (S_{irt} - S_{jrt}) &= (\alpha_i - \alpha_j) + \beta_2 (D_{1t} - D_{2t}) + (\beta_3 - \lambda_3)\tau_t \\ &\quad + (\beta_4 - \lambda_4)W_{rt} + \gamma BSC_t + (e_{irt} - \varepsilon_{jrt}). \end{aligned}$$

To investigate the idea that there was a heterogeneous impact of the introduction of the Balanced Scorecard we extend this specification to allow the impact of the Balanced Scorecard to vary with managerial experience, $\gamma = \gamma_0 + \gamma_1 Experience_i$.

4. Results

4.1 The overall impact of the balanced scorecard

We start in Table 6 by considering how we parameterise the BSC variables. The dependent variable is the difference in sales between the matched branches. In the first column we include an indicator for just the two years that the incentive scheme was in place (August 2002 to July 2004) - so we are comparing the level of sales in brand A branches with brand C branches during this period with the difference in the level before and after this period. This shows that sales in brand A branches increased by an average of £4,538 per month more than brand C branches during the two year period in which the Balanced Scorecard was in place. In column (2) we split this period in half and see that the impact was similar across the two years. In column (3) we also include an indicator for the year after the firm put the incentive scheme on hold - so we are now comparing just to the two years before the Balanced Scorecard was implemented. We now see a larger impact around (£8,305) which diminishes slightly over time. In column (4) we consider whether there was an anticipation effect in the initial discussion period (i.e. a Hawthorne effect in anticipation of the actual implementation), but find no evidence of this. For the remainder of this paper we stick to the parameterisation in column (3). In Table 6 we also see that demand for brand C products grew somewhat faster than brand A products (the coefficient on demand is negative), that there is more demand for brand A products when it is hotter, and less when it is raining (this makes sense as brand is more often used outside).

These results suggest that the Balanced Scorecard had an impact on increasing sales, but what about profits? In Table 7 we look at how gross profits, trading profits, labour costs, infrastructure expenditure, transport costs, general and administrative costs, information technology expenditure, local marketing and advertising expenditure and other costs were effected.

The first column of Table 7 repeats column (3) of Table 6. All regressions include controls for aggregated demand, the weather, month and branch effects. In column (2) we see that there was also a corresponding increase in gross profits (the difference between sales and gross profits is the cost of goods sold). In column (3) we see that this did not feed through into an increase in trading profits, and in fact led to a fall in profits in the later period of on average -£1,018. The difference between gross and trading profits is the costs considered in columns (5)-(10). The fall in profits arose largely because transport costs (column 6) and labour costs increased (column 4), and to a lesser extent because infrastructure (column 5) and general and administrative costs (column 7) increased. Other and IT costs actually fell.

This is the first empirical result of the paper - the Balanced Scorecard lead to an increase in sales, but costs increased by at least as much as sales at the aggregated branch level, so there was no increase (and actually some decrease) in profits.

4.2 Did the balanced scorecard target the right tasks?

One important question is whether the Balanced Scorecard targeted the right tasks - i.e. tasks that would improve performance. Did branches that improved on the non-financial aspects measured subsequently experienced improved performance? Did the Balanced Scorecard correctly identify the key drivers of performance? We use the data collected under the Balanced Scorecard to distinguish between branches that successfully put effort into improving on the non-financial measures from those which did not. For each branch we calculate what proportion of the total non-financial points that were available they earned. This ranges from 16% to 74% and has a median value of 52%.

In Table 8 we split the sample into those branches that were below and above the median share of points earned on the non-financial measures. In the top half of Table 8 we consider the change in outcomes of those branches that either did not try, or were not able, to perform well on the non-financial measures, and in the bottom half those branches that did well on the non-financial measures.

Here we see large differences between the two groups. In the top panel branches that did poorly on non-financial measures did not experience any significant growth in sales, but they did experience some increases in costs, leading to reduced trading profits. In contrast, those branches that did well on the non-financial measures saw an increase in sales, gross profits and trading profits. While costs did increase in these branches, sales increased by more, resulting in higher profits.

Figure 3 shows a similar picture. Each dot represents a brand a branch. The x-axis shows the share of possible non-financial points earned, and the y-axis shows branch profits (scaled by sales). The correlation between these is 0.66 and is statistically significant.

Figure 3: Comparison of non-financial with financial performance during Balanced Scorecard

Notes: 156 observations (one for each Division 1 Brand A branch); x-axis is the share that each branch earned of the total points they could have earned on the non-financial BSC measures (customer, internal, people and supplier) over the period August 2002 - July 2004; y-axis is the share that each branch earned of the total points they could have earned on the financial BSC measures over the period August 2002 - July 2004.

One concern is that this could simply be showing that good branches (or good branch managers) do well on both financial and non-financial indicators. Proponents of the Balanced Scorecard argue that giving branches an incentive to put effort into a broader range of factors that feed into long run performance will lead to better performance in the long run. Opponents of the Balanced Scorecard argue that giving managers and workers so many different incentive will lead to worse performance as individuals lose focus and put too much effort into the easiest tasks. To investigate this we make a further comparison. We consider branch financial performance during three time periods - prior to the Balance Scorecard (August 1999 - July 2002), during the Balanced Scorecard (August 2002 - July 2004) and after (August 2004 - July 2005).

Figure 3b: Comparison of non-financial with financial performance during the Balanced Scorecard, using profits over sales rather than BSC measures.

Notes: 156 observations (one for each Division 1 Brand A branch); x-axis is the share that each branch earned of the total points they could have earned on the non-financial BSC measures (customer, internal, people and supplier) over the period August 2002 - July 2004; y-axis is the share that each branch earned of the total points they could have earned on the financial BSC measures over the period August 2002 - July 2004.

In Figures 3 and 3b we show that good performance on the non-financial points during the Balanced Scorecard also led to good financial performance afterwards. In Figure 4 we split by financial performance in the period before the Balanced Scorecard was introduced. The relationship is stronger in those branches which previously performed badly than in those that did well (correlation coefficient (p-value) of 0.727 (0.000) and 0.346 (0.002) respectively).

Figure 4: Comparison of non-financial with financial performance during Balanced Scorecard, split by financial performance before BSC

Notes: 156 observations (one for each Division 1 Brand A branch); x-axis is the share that each branch earned of the total points they could have earned on the non-financial BSC measures (customer, internal, people and supplier) over the period August 2002 - July 2004; y-axis is the average value of trading profits over sales for each branch over the period August 2002 - July 2004; left-hand panel are those branches that had below median ratio of profit to sales over the period August 1999 - July 2002.

In Figure 5 we show this same picture separately for branches that did poorly in financial terms in the period before the Balanced Scorecard and those that did well, and we see a positive effect in both cases.

Figure 5: Comparison of non-financial with financial performance after Balanced Scorecard

Notes: 156 observations (one for each Division 1 Brand A branch); x-axis is the share that each branch earned of the total points they could have earned on the non-financial BSC measures (customer, internal, people and supplier) over the period August 2002 - July 2004; y-axis is the average value of trading profits over sales for each branch over the period August 2004 - July 2005.

These pictures are suggestive, but we haven't controlled for any of the local economic time varying factors we were concerned with above. To do this we return to the regressions of the form of equation (4) and we compare performance in four groups of branches - (1) those who did badly on financial measures prior to implementation of the Balanced Scorecard, and who subsequently also did badly on non-financial measures during the implementation of the Balanced Scorecard, (2) those who did badly on financial measures prior to implementation and well on non-financial during implementation, (3) those who did well on financial measures prior but badly on non-financial during, and (4) those who did well on financial prior and well on non-financial during.

Figure 6: Comparison of non-financial with financial performance after Balanced Scorecard, split by financial performance before BSC

Notes: 156 observations (one for each Division 1 Brand A branch); x-axis is the share that each branch earned of the total points they could have earned on the non-financial BSC measures (customer, internal, people and supplier) over the period August 2002 - July 2004; y-axis is the average value of trading profits over sales for each branch over the period August 2004 - July 2005; left-hand panel are those branches that had below median ratio of profit to sales over the period August 1999 - July 2002.

The top panel of Table 9 shows the estimates for group (1), the bottom panel for group (2), the top panel of Table 8b shows the estimates for group (3) and the bottom panel for group (4).

What we see is a pattern that suggests that branches that do well on the non-financial measures also do well on financial measures. In particular, those branches that previously did badly on financial measures (bottom panel of Table 9a) had substantially higher sales during implementation period and less so after. While costs increased, sales increased by more, so that trading profits also increased.

Consider the branches that did well financially prior to implementation. Those that did badly on non-financial measures (top panel of Table 9b) did badly in financial terms after implementation, while those that did well on non-financial measures (bottom panel of Table 9b) did well in financial terms after implementation.

The second empirical result of the paper is to show that those branches that were successful on the non-financial measures also did well financially. The results also suggest that there was heterogeneity in the effect of the Balanced Scorecard across branches. We now turn to investigate what might explain this heterogeneity.

Table 9: Years of service

4.3 The importance of experience

From a theoretical perspective why should the impact of the balanced scorecard vary by the experience of managers? Some studies have argued that less experienced managers rely on formal measurement systems to supplement their inexperience, more than experienced managers (Bourne et al, 2005). We find the opposite, that the more experienced the manager the greater the impact of the balanced scorecard. As an incentive scheme there is no obvious reason why more experienced managers should be more motivated by the incentive scheme than less experienced managers (if anything, we might think the opposite as the incentive will account for a lower share of their total income). The consumer psychology literature makes an important distinction is made between motivation, ability and opportunity (Batra and Ray, 1986; Andrews, 1988; MacInnis et al. 1991), which is also discussed in the organisation design and psychology literatures (Parker and Wall, 1998). This literature makes explicit the distinction between: **Opportunity** (the freedom and scope to act), **Motivation** (the incentives to respond), and **Ability** (whether an individual has the necessary skills and capabilities to respond). The point made in both the consumer psychology and organisation design literatures is that the absence of any of the above factors significantly limits the likelihood either of action or the impact of action. In the case of the balanced scorecard it is clear that there is an incentive for managers to act – hence the motivation is in place – but do they have the opportunity and the ability to act? And are the answers to these questions affected by their experience?

To investigate this we undertook 20 systematic telephone interviews with branch managers. The branch managers selected for interview had all been with the firm for at least four years, hence they had been in post for the entire period during which the Balanced Scorecard operated. Each interview lasted between 45-75 minutes, during which time branch managers were asked a series of questions about their experiences with the Balanced Scorecard. Initially the interviewees were asked to explain when they first heard about the Balanced Scorecard and what their initial reactions were to the scheme. Next they were asked to explain how they introduced the Balanced Scorecard to their staff and to comment on the staff's reaction to the scheme. Third the interviewees were asked to explain how they used the Balanced Scorecard and how they involved their staff in discussing the results. Fourth they were asked to comment on what happened to the Balanced Scorecard over the time it was in operation. Finally they were asked to comment on how they measured and managed performance in their branches today (post the Balanced Scorecard).

From the interviews we found that, while the majority of managers interviewed were positive about the scheme, several raised issues that lead us to question whether they were able to act on the data. The first common theme to arise was the issue of data quality: *"I think one of the problems straight away was we didn't have the ability to measure a lot of the measures correctly or the figures were wrong"* – Branch Manager A.

The second was whether the measures were under the manager's control.

“Personally, we would discuss why it had happened and we would put an action plan in, just a vehicle for action plan, what we could try and do to improve the score, but there were certain measures that you couldn't control like your cash collection. If a customer had no money, there was absolutely nothing you could do to encourage them to pay the bill, so that was totally out of your control” – Branch Manager B.

“Quite honestly, I used to look at the control card and I used to see oranges, I used to see the yellows, I used to see the greens and I knew which ones I could influence easily. Okay, and I could do something about those and I would do it. The ones I couldn't do, I just had to leave” – Branch Manager C.

Taken together – these two issues – the quality of the data and the question of whether the measures were under the managers' control, clearly have an impact on a manager's opportunity and ability to act, as well as their motivation to act. Poor quality data undermines the managers' confidence in the scheme, causing them to question whether the scheme is encouraging appropriate behaviour.

Interestingly, the issue of control over the measures is a factor that many managers raised, but then some found solutions to. For example, one experienced manager, explained the local work around that he and his team had developed to enable him to act on the customer retention data that other managers said they had no control over.

“I mean the staff that I've got on the counter have been with me for years and they will come in and say we haven't seen Brian. If they tell you this bloke hasn't been in for a week or so, you can do something about it” – Branch Manager D.

The interview data suggest that the more experienced managers found ways of overcoming the constraints of the balanced scorecard. They did not allow issues of opportunity and ability to hamper their ability to act on the balanced scorecard data, because their experience enabled them to identify ways of overcoming these constraints.

We wanted to explore the idea that more experienced managers were better able to utilise the information in the Balanced Scorecard. The number of interviews was not sufficient to allow us to analyse the response systematically. Instead, we used information from the firm's payroll system. We use information on the years of experience of staff in each branch to look at whether more experienced workers, and in particular more experienced managers, responded better to the Balanced Scorecard.

Table 10 repeats the results in Table 7 but allowing the impact of the Balanced Scorecard to vary with the average years of experience of all staff. Before considering these results, we note that a simple correlation in the data is consistent with the idea

that more experienced managers achieve better performance. The correlation between years of managerial experience and profits is 0.36 (significant at the 1% level). Turning to the results, in the first three columns of Table 10 we see that experience matters. A branch with staff with the average years of experience (6.6 years) will have a £400 higher level of trading profits after the Balanced Scorecard was introduced than a branch with all new staff. In the second three columns we show that it is the years of experience of senior staff that matters most. A branch with senior staff with the average years of experience (11.3 years) will have around £200 higher level of trading profits after the Balanced Scorecard was introduced than a branch with all new senior staff.

In results not shown (available from authors on request) we include the average age of all staff and of senior staff interacted with the Balanced Scorecard indicators and show that it is experience, not age, that is important. Also in results not shown (available from authors on request) we show that if we simply split the sample on whether the manager has more or less than 10 years experience (approximately the median) we see all of the effect of the Balanced Scorecard in the greater than 10 years experience group.¹⁴

5. Summary and conclusions

Our results suggest that the balanced scorecard had some impact, and that this impact varied significantly by branch. Sales increased on average across all branches, but costs increased by at least as much, so that while gross profits did increase, trading profits did not increase. There is significant variation in the impact. When we separate those branches that perform well on non-financial measures from those that perform poorly on non-financial performance measures we find that the first group – those that perform well on non-financial measures – experience statistically significant increases in sales, gross profits and trading profits. One potential explanation of this finding is that branches that perform well on non-financial measures and financial measures are simply well managed. Note that we are allowing for each branch to have a different average level of performance (we include branch fixed effects). To consider this further we split the sample into branches that perform relatively well and those that perform relatively poorly on financial measures in the pre-implementation period. We then explore whether there are differences in non-financial and financial performance in the implementation period. We find that, regardless of prior performance, branches that perform well on non-financial measures also perform well on financial measures.

---

¹⁴ The coefficients (standard errors) on the Balanced Scorecard variables are for the branches with managers with *less* than 10 years experience: (Aug 2002-Jul2003) 206 (968); (Aug 2003 - Jul 2004) 70 (847); Aug 2004 - Jul 2005) -1850 (796); for the branches with managers with *more* than 10 years experience: (Aug 2002-Jul2003) 1854 (896); (Aug 2003 - Jul 2004) 2218 (846); Aug 2004 - Jul 2005) -1339 (709).

* significant at 10%; ** significant at 5%; *** significant at 1%

This finding is particularly important as it suggests that the balanced scorecard, when implemented correctly and adopted by the branches, has a positive impact on branch performance in terms of sales, gross profit and net profit.

We then show that years of experience is an important factor in explaining these differences in performance. More experience managers were able to improve performance. We interpret this as suggesting that the information content of the Balanced Scorecard is what is important, not the incentive per se.

Crucially the research reported in this paper suggests that multi-dimensional performance measurement systems can have a positive impact on a firm's financial performance providing the measures and the associated data are presented in a way that enables managers and staff to act on them. It is not enough to introduce an incentive scheme that relates to the measures, unless that incentive scheme is accompanied by data that are meaningful to those who have to manage and improve performance. Too often, when performance measurement systems and associated incentive schemes are introduced they are not designed to enable staff at the front line to take action. The schemes are too complex and contain data which are not sufficiently disaggregated to enable action to be taken. How to designing measurement and incentive schemes configured for action is a significant challenge for future research.
